Abstract

This paper summarises the capabilities of the \texttt{Xy-pic} package for typesetting graphs and diagrams within \texttt{TeX}.

A characteristic of \texttt{Xy-pic} is that it is build around a \textit{kernel drawing language} which is a concise notation for general graphics, \textit{e.g.},

\begin{verbatim}
\xy (3,0)*+[F]{A} ; (20,6)*+[F]{B} \dir{} **\dir{-} ? *!/_3pt/\dir{} *!/_!7pt/\dir{} ?\dir{>}
\end{verbatim}

was drawn by the \texttt{Xy-pic} kernel code

\begin{verbatim}
\def\xymatrixsymbol{A} \def\xymatrixsymbol{B} \xymatrix{} \end{verbatim}

It is an object-oriented graphic language in the most literal sense: ‘objects’ in the picture have ‘methods’ describing how they typeset, stretch, etc., however, the syntax is rather terse.

Particular applications make use of \textit{extensions} that enhance the graphic capabilities of the kernel—in fact the kernel is quite useless without any extensions that handle such diagrams as

\begin{verbatim}
\hbox{Square} \hbox{Round} \hbox{Bend}
\end{verbatim}

which was typeset by

\begin{verbatim}
\xymatrix\text{Square} \text{Round} \text{Bend}
\end{verbatim}

using the ‘\texttt{curve}’ and ‘\texttt{frame}’ extension.

All this is made accessible through \textit{features} that provide convenient notation such that users can enter special classes of diagrams in an intuitive form, \textit{e.g.}, commutative diagrams are catered for by the ‘matrix’ and ‘arrow’ features with which the diagram

\begin{verbatim}
\xymatrix{ U & X \\ X \times_Z Y & Y \ar[r] \ar[d] & X \ar[d] \ar[r] & Z \ar[l] }\end{verbatim}

was typeset by the \texttt{Xy-pic} input lines

\begin{verbatim}
\xymatrix{ U \arrow{0} \arrow{1} \arrow{2} \ar[r] \ar[d] & X \\ X \times_Z Y \ar[d] \ar[r] \ar[d] & Y \ar[r] & Z \ar[l] }
\end{verbatim}

We will not describe the combination of features in this manual: refer to the User’s Guide [8] for a tutorial on how diagrams like the above can be typeset.

The current implementation is programmed completely within “standard \texttt{TeX} and \texttt{METAFONT}, \textit{i.e.}, using \texttt{TeX} macros (no \texttt{specials}) and fonts designed using \texttt{METAFONT}. Optionally a special ‘backend’ makes it possible to produce DVI files with ‘specials’ for \texttt{PostScript}\textsuperscript{1} drivers.

\textsuperscript{1}PostScript is a trademark of Adobe, Inc.

Part I
The Kernel

After giving an overview of the \texttt{xy-pic} environment in §1 we document the basic concepts of \texttt{xy-pic} construction in §2, including the maintained ‘graphic state’. The following sections give the precise syntax rules of the main \texttt{xy-pic} constructions: the position language in §3, the object constructions in §4, and the picture ‘decorations’ in §5. §6 presents the kernel repertoire of objects for use in pictures; §7 documents the interface to \texttt{xy-pic} options like the standard ‘feature’ and ‘extension’ options.

Details on the implementation are not discussed in this paper but in the complete \texttt{TeX}nical documentation [5].

Notation

We will give descriptions of the syntax of pictures as BNF rules; in explanations we will use upper case letters like X and Y for (dimen)sions and lower case like x and y for (factor)s.

1 The \texttt{xy-pic} implementation

This section briefly discusses the various aspects of the present \texttt{xy-pic} kernel implementation of which the user should be aware in order to experiment with it.

1.1 Loading \texttt{xy-pic}

\texttt{xy-pic} is careful to set up its own environment in order to function with a large variety of formats. For most formats a single line with the command
\begin{verbatim}
\input xy
\end{verbatim}
in the preamble of a document file should load the kernel (see ‘integration with standard formats’ below for variations possible with certain formats, in particular \texttt{EPiX}).

The rest of this section describes things you must consider if you need to use \texttt{xy-pic} together with other macro packages, style options, or formats. The less your environment deviates from plain \texttt{TeX} the easier it should be. Consult the \texttt{TeX}nical documentation [5] for the exact requirements for other definitions to coexist with \texttt{xy-pic}.

Privacy: \texttt{xy-pic} will warn about control sequences it redefines—thus you can be sure that there are no conflicts between \texttt{xy-pic}-defined control sequences, those of your format, and other macros, provided you load \texttt{xy-pic} last and get no warning messages like

\texttt{xy-pic Warning: ‘...’ redefined.}

In general the \texttt{xy-pic} kernel will check all control sequences it redefines except that (1) generic temporaries like \texttt{\newcommand} are not checked, (2) predefined font identifiers (see §1.3) are assumed intentionally preloaded, and (3) some of the more exotic control sequence names used internally (like \texttt{\*dir00-0}) are only checked to be different from \texttt{relax}.

Category codes: Unfortunately the situation is complicated by the flexibility of \texttt{TeX}'s input format. The culprit is the ‘category code’ concept of \texttt{TeX} (cf. [2, p.37]): when loaded \texttt{xy-pic} requires the characters \texttt{\emph{|\texttt{X}}}, the first is a space) to have their standard meaning and all other printable characters to have the same category as when \texttt{xy-pic} will be used—in particular this means that (1) you should surround the loading of \texttt{xy-pic} with \texttt{\texttt{\makeatletter}} \texttt{\makeatother} \texttt{\texttt{\makeatletter}} when loading it from within a \texttt{EPiX} package, and that (2) \texttt{xy-pic} should be loaded after files that change category codes (like the \texttt{german.sty} that makes " active).

Integration with standard formats The integration with various formats is handled by the \texttt{xyidioms.tex} file and the integration as a \texttt{EPiX} style option by \texttt{xy.sty}:

\begin{verbatim}
\input xy
\end{verbatim}

\texttt{xyidioms.doc} This included file provides common idioms whose definition depends on the used format such that \texttt{xy-pic} can use predefined dimension registers etc. and yet still be independent of the format under which it is used. The current version (2.9) handles plain \texttt{\texttt{\TeX}} (version 2 and 3), \texttt{\texttt{\AMSTeX}} (version 2.0 and 2.1), \texttt{\texttt{\LaTeX}} (version 2.09 and 2e), \texttt{\texttt{\LaTeXe}} (version 1.0 and 1.1), and \texttt{\texttt{\LaTeXe}} (version 2.6)

\texttt{xy.sty}: If you use \texttt{\texttt{\LaTeX}} then this file makes it possible to load \texttt{xy-pic} as a ‘package’ using the \texttt{\texttt{\LaTeXe}} \texttt{\usepackage} command:
\begin{verbatim}
\usepackage [(option),...]{xy}
\end{verbatim}

\footnote{Although there is a name conflict between the ‘arrow’ feature and \texttt{\texttt{\LaTeXe}} that also defines \texttt{\arrow}.}
where the (option)s will be interpreted as if passed to `\xyoption` (cf. §7). Furthermore driver package options (cf. [1, table 11.2, p.317]) will invoke the appropriate backend (see §19).

The file also works as a \TeX\ 2.09 ‘style option’ although you will have to load options with the \XeTeX mechanism.

1.2 Logo, version, and messages

Loading \XeTeX prints a banner containing the version and author of the kernel; small progress messages are printed when each major division of the kernel has been loaded. Any options loaded will announce themselves in a similar fashion.

If you refer to \XeTeX in your written text (please do ☺) then you can use the command `\XY-pic` to typeset the ‘\XeTeX’ logo. The version of the kernel is typeset by `\xyversion` and the release date by `\xydate` (as found in the banner). By the way, the \XeTeX name⁴ originates from the fact that the first version was little more than support for \((x, y)\) coordinates in a configurable coordinate system where the main idea was that all operations could be specified in a manner independent of the orientation of the coordinates. This property has been maintained except that now the package allows explicit absolute orientation as well.

Messages that start with ‘\XeTeX Warning’ are indications that something needs your attention; an ‘\XeTeX Error’ will stop \TeX\ because \XeTeX does not know how to proceed.

1.3 Fonts

The \XeTeX kernel implementation makes its drawings using five specially designed fonts:

<table>
<thead>
<tr>
<th>Font</th>
<th>Characters</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>\xdashfont</code></td>
<td>dashes</td>
<td><code>\xdash10</code></td>
</tr>
<tr>
<td><code>\yatipfont</code></td>
<td>arrow tips, upper half</td>
<td><code>\yatip10</code></td>
</tr>
<tr>
<td><code>\ybtipfont</code></td>
<td>arrow tips, lower half</td>
<td><code>\ybtip10</code></td>
</tr>
<tr>
<td><code>\ybsqfont</code></td>
<td>quarter circles for</td>
<td><code>\ybsq10</code></td>
</tr>
<tr>
<td></td>
<td>hooks and squiggles</td>
<td></td>
</tr>
<tr>
<td><code>\ycircfont</code></td>
<td>1/8 circle segments</td>
<td><code>\ycirc10</code></td>
</tr>
</tbody>
</table>

The first four contain variations of characters in a large number of directions, the last contains 1/8 circle segments.

Note: The default fonts are not part of the \XeTeX kernel specification: they just set a standard for what drawing capabilities should at least be required by an \XeTeX implementation. Implementations exploiting capabilities of particular output devices are in use. Hence the fonts are only loaded by \XeTeX if the control sequence names are undefined—this is used to preload them at different sizes or prevent them from being loaded at all.

1.4 Allocations

One final thing that you must be aware of is the fact that \XeTeX allocates a significant number of dimension registers and some counters, token registers, and box registers, in order to represent the state and do computations. The \XeTeX v.2.10 kernel allocates 6 counters, 27 dimensions, 2 box registers, 3 token registers, 1 read channel, and 1 write channel (when running under plain \TeX\; under \TeX\ and \AmSTeX slightly less is allocated because the provided temporaries are used). Options may allocate further registers.

2 Picture basics

The basic concepts involved when constructing \XeTeX pictures are positions and objects, and how they constitute a state used by the graphic engine.

The general structure of an \XeTeX-picture is as follows:

```
\xy⟨pos⟩ ⟨decor⟩ \endxy
```

builds a box with an \XeTeX picture (\TeX\ users may substitute \texttt{\begin{xy} ... \end{xy}} if they prefer). \langle pos⟩ and \langle decor⟩ are components of the special ‘graphic language’ which \XeTeX-pictures are specified in. We explain the language components in general terms in this § and in more depth in the following §§.

2.1 Positions

All positions may be written \langle \(X, Y\rangle \rangle where \(X\) is the \TeX\ dimension distance \textit{right} and \(Y\) the distance \textit{up} from the zero position \(0\) of the \XeTeX-picture (\(0\) has coordinates \langle \texttt{0mm}, \texttt{0mm}⟩, of course). The zero position of the \XeTeX-picture determines the box produced by the \texttt{\xy}...\texttt{\endxy} command together with the four parameters \(X_{\text{min}}, Y_{\text{min}}, X_{\text{max}}, Y_{\text{max}}\) set such that all the objects in the picture are ‘contained’ in the following rectangle:

```
\begin{center}
\begin{tikzpicture}
\draw (0,0) rectangle (4,4);
\end{tikzpicture}
\end{center}
```

where the distances follow the “up and right \(> 0\)” principle, e.g., the indicated \TeX reference point has coordinates \langle \(X_{\text{min}}, 0\text{pt}\rangle \rangle within the \XeTeX-picture. The zero
2.2 Objects

The simplest form of putting things into the picture is to ‘drop’ an object at a position. An object is like a TeX box except that it has a general Edge around its reference point—in particular this has the extent (i.e., it is always contained within) the dimensions $L$, $R$, $U$, and $D$ away from the reference point in each of the four directions left, right, up, and down. Objects are encoded in TeX boxes using the convention that the TeX reference point of an object is at its left edge, thus shifted $<-L, 0\text{pt}>$ from the center—so a TeX box may be said to be a rectangular object with $L = 0\text{pt}$. Here is an example:

```
\begin{tikzpicture}
  \draw (0,0) rectangle (2,2);
\end{tikzpicture}
```

The object shown has a rectangle edge but others are available even though the kernel only supports rectangle and circle edges. It is also possible to use whole \texttt{Xy-pic} pictures as objects with a rectangle edge, 0 as the reference point, $L = -X_{\text{min}}$, $R = X_{\text{max}}$, $D = -Y_{\text{min}}$, and $U = Y_{\text{max}}$. The commands for objects are described in §4.

2.3 Connections

Besides having the ability to be dropped at a position in a picture, all objects may be used to connect the two current objects of the state, i.e., $p$ and $c$. For most objects this is done by ‘filling’ the straight line between the centers with as many copies as will fit between the objects:

```
\begin{tikzpicture}
  \draw (0,0) -- (2,2);
\end{tikzpicture}
```

The ways the various objects connect are described along with the objects.

2.4 Decorations

When the \texttt{\textbackslash xy} command reaches something that can not be interpreted as a continuation of the position being read, then it is expected to be a decoration, i.e., in a restricted set of TeX commands which add to pictures. Most such commands are provided by the various \texttt{user options} (cf. §7)—only a few are provided within the kernel to facilitate programming of such options (and user macros) as described in §5.

2.5 The \texttt{Xy-pic} state

Finally we summarise the user-accessible parts of the \texttt{Xy-pic} picture state of two positions together with the last object associated with each: the previous, $p$, is the position $<X_p, Y_p>$ with the object $L_p$, $R_p$, $D_p$, $U_p$, $Edge_p$, and the current, $c$, is the position $<X_c, Y_c>$ with the object $L_c$, $R_c$, $D_c$, $U_c$, $Edge_c$.

Furthermore, \texttt{Xy-pic} has a configurable cartesian coordinate system described by an origin position $<X_{\text{origin}}, Y_{\text{origin}}>$ and two base vectors $<X_{\text{base}}, Y_{\text{base}}>$ and $<X_{\text{base}}, Y_{\text{bar}}>$, and accessed by the usual notation using parentheses:

\[ (x, y) = <X_{\text{origin}} + x \times X_{\text{base}} + y \times Y_{\text{base}}, \]
\[ Y_{\text{origin}} + x \times Y_{\text{bar}} + y \times Y_{\text{bar}} > \]

This is explained in full when we show how to set the base in note 3d of §3.

Finally typesetting a connection will setup a “placement state” for referring to positions on the connection that is accessed through a special \texttt{position} construction; this is also discussed in detail in §3.

The \texttt{Xy-pic} state consists of all these parameters together. They are initialised to zero except for $X_{\text{base}} = Y_{\text{base}} = \text{mm}$. The dimension parameters are directly available as TeX \texttt{dimen} registers with the obvious names: $\text{Xmin}$, $\text{Xmax}$, $\text{Ymin}$, and $\text{Ymax}$, $\text{Xp}$, $\text{Yp}$, $\text{Dp}$, $\text{Up}$, $\text{Lp}$, and $\text{Ip}$; $\text{Xc}$, $\text{Yc}$, $\text{Dc}$, $\text{Uc}$, $\text{Lc}$, and $\text{Ic}$; $\text{Xorigin}$, $\text{Yorigin}$, $\text{Xbase}$, $\text{Ybase}$, $\text{Xbar}$, and $\text{Ybar}$.

The edges are not directly available (but see the technical documentation for how to access them).

3 Positions

A \texttt{position} is a way of specifying locations as well as dropping objects at them and decorating them—in fact any aspect of the \texttt{Xy-pic} state can be changed by a \texttt{position} but most will just change the coordinates and/or shape of $c$.

All possible positions are shown in figure 1 with explanatory notes below.

\textbf{Exercise 1:} Which of the positions $0$, $<0\text{pt}, 0\text{pt}>$, $<0\text{pt}>$, $(0, 0)$, and $/0\text{pt}$ is different from the others?

\textbf{Notes}

3a. When doing arithmetic with \texttt{+} and \texttt{-} then the resulting object inherits the size of the \texttt{coord}, i.e., the right argument—this will be zero if the \texttt{coord} is a \texttt{vector}.

</tbody>
</table>

Figure 1: ⟨positions⟩.
Exercise 2: How do you set $c$ to an object the same size as the saved object "ob" but moved $<X, Y>$?

3b. **Skewing** using ! just means that the reference point of $c$ is moved with as little change to the shape of the object as possible, i.e., the edge of $c$ will remain in the same location except that it will grow larger to avoid moving the reference point outside $c$. ! is useful in conjunction with (corner) positions to do things like

The dotted frame around this text was created by first building the object with the solid frame, then extending it with !LD !<3pt> !R0 !<3pt>, and finally connecting the corners with dots.

**Bug:** The result of ! is always a rectangle currently.

Exercise 3: What does the (pos) ...!R-L do?

3c. A (pos) `covers` another if it is a rectangle with size sufficiently large that the other is "underneath". The . operation "extends" a (pos) to cover an additional one—the reference point of $c$ is not moved but the shape is changed to a rectangle such that the entire $p$ object is covered.

3d. The operations : and :: set the base used for (coordinate)s on the form $(x, y)$. The : operation will set $X_{\text{origin}}$, $Y_{\text{origin}}$ to $p$, $X_{\text{base}}$, $Y_{\text{base}}$ to $c - \text{origin}$, and $X_{\text{phase}}$, $Y_{\text{phase}}$ to $<-Y_{\text{base}}$, $X_{\text{base}}>$ (this ensures that it is a usual square coordinate system). The :: operation may then be used afterwards to make nonsquare bases by just setting $y_{\text{base}}$ to $c - \text{origin}$. Here are two examples $0; <1\text{cm}, 0\text{cm}>$: will set the coordinate system

$$\begin{array}{c}
\text{origin} \\
\downarrow
\end{array} \quad \begin{array}{c}
y_{\text{base}} \\
x_{\text{base}}
\end{array} \quad \times (1, 1)$$

and $<1\text{cm}, .5\text{cm}>; <2\text{cm}, 1.5\text{cm}>; <1\text{cm}, 1\text{cm}>::$ will define

$$\begin{array}{c}
y_{\text{base}} \\
\downarrow
\end{array} \quad \begin{array}{c}
y_{\text{base}} \\
x_{\text{base}}
\end{array} \quad \times (1, 1)$$

before

\[ \circ \]

\[ \downarrow \]

\[ \text{origin} \]

where in each case the $\circ$ is at 0, the base vectors have been drawn, and the $\times$ is at $(1, 1)$.

3e. To drop an (object) at $c$ with * means to actually physically typeset it in the picture with reference position at $c$—how this is done depends on the (object) in question and is described in detail in §4. The intuition with a drop is to do something that typesets something a $<X, c, Y>$ and sets the edge of $c$ accordingly.

3f. The `connect` operation ** will first compute a number of internal parameters describing the direction from $p$ to $c$ and then typesets a connection filled with copies of the (object) as illustrated in §2.3. The exact details of the connection depend on the actual (object) and are described in general in §4. The intuition with a connection is that it is something that typesets something connecting $p$ and $c$ sets the ?(pos) operator up accordingly.

3g. Using ? will "pick a place" along the most recent connection typeset with **. What exactly this means is determined by the object that was used for the connection and by the modifiers described in general terms here.

The "shave" modifiers in a (place), < and >, change the default (factor), $f$, and how it is used, by 'moving' the positions that correspond to (0) and (1) (respectively): These are initially set equal to $p$ and $c$, but shaving will move them to the point on the edge of $p$ and $c$ where the connection "leaves/enters" them, and change the default $f$ as indicated. When one end has already been shaved thus then subsequent shaves will correspond to sliding the appropriate position(s) a \TeX \jot (usually equal to 3pt) further towards the other end of the connection (and past it). Finally the pick action will pick the position located the fraction $f$ of the way from (0) to (1) where $f = 0.5$ if it was not set (by <, >, or explicitly).

Finally, the (slide) will move the position a dimension further along the connection at the picked position. For straight connections (the only ones kernel \TeX provides) this is the same as adding a vector in the tangent direction, i.e., ?.../A/ is the same as ?...+A/.

All this is probably best illustrated with some examples: each \@ in figure 2 is typeset by a sequence of the form $p; c **\dir{.} ?(\text{place}) *\oplus$ where we indicate the ?(place) in each case.

3h. The positions denoted by the axis intersection (coordinate)s in a and $y$ are the points where the line through $p$ and $c$ intersects with each axis. These are probably best illustrated by the following example where they are shown for a coordinate sys-
3i. A (pos) (decor) grouped in \{\}-braces is interpreted in a local scope in the sense that any p and base built within it are forgotten afterwards. **Remark:** Only p and base are restored—it is not a \LaTeX{} group.

**Exercise 5:** What is the effect of the (coordinate)inate \{3,1\}?"?

3j. The vector /Z/, where Z is a (dimension)ion, is the same as the vector \(Z \cos \alpha, Z \sin \alpha\) where \(\alpha\) is the angle of the last direction set by a connection (**) or subsequent placement (?). It is possible to give a (direction) as described in the next section (note 4i in particular) that will then be used to set the value of \(\alpha\).

3k. A (corner) is an offset from the current \(<X_c,Y_c>\) position to a specific position on the edge of the c object (the two-letter ones may be given in any combination):

The ‘proportional’ point P is computed in a complex way to make the object look as much ‘away from p’ as possible.

Finally, a following (f) suffix will multiply the offset vector by the (factor) f.

**Exercise 6:** What is the difference between the (position) c< and c+E?

**Exercise 7:** What does

\begin{verbatim}
\textbf{xy} *=<3cm,1cm>\textit{\{Box\}}*\textbf{\{frm\}}
!U!R(.5) *\{frm\}.*\{bullet\} \end{verbatim}

... typeset? **Hint:** \textbf{frm} is defined by the frame extension and just typesets a frame of the kind indicated by the argument.

**Bug:** Currently only the single-letter corners (L, R, D, U, C, E, and F) will work for any shape—the others silently assume that the shape is rectangular.

3l. The stack is a special construction useful for storing a sequence of (position)ation. \$i initialises, i.e., clears the stack such that it contains no positions, \$+ ‘pushes’ c onto it, i.e., adds on the ‘top’ of the
stack, increasing the ‘depth’ by one, and $\emptyset$—‘pops’ the top element off the stack, decreasing the depth by one. It is an error to pop when the stack is empty.

The special (coord)inates $s_n$, where $n$ is either a single digit or a positive integer in $\{s\}$, refer to the $n$’th position below the top, i.e., $s0$ is the position on the top, $s1$ the one below that, etc. The depth of the stack minus one is called \textbackslash{sdepth} hence the bottom element of the stack is accessed by the (coord) $s(\textbackslash{sdepth})$.

\textbf{Exercise 8:} Assume the positions $A$, $B$, $C$, and $D$ are defined. What does the stack contain after the (position) $\mathbf{0i}$, $A\mathbf{0+}$, $B\mathbf{0+}$, $\mathbf{0-}$, $C$, $D\mathbf{0+}$?

\textbf{To Do:} Allow repeat of push and pop to get the effect of a multiput.

3m. To ‘do (coord) for every stack element’ means to set $c$ to all the elements of the stack, from the bottom up, and for each interpret the (coord). Thus the first interpretation has $c$ set to $s(\textbackslash{sdepth})$ and the last has $c$ set to $s0$. If the stack is empty, the (coord) is not interpreted at all.

This can be used to repeat a particular (coord) for several points:

\begin{verbatim}
\x y
  \mathbf{0i} \mathbf{0+}(0,-10) \mathbf{0+}(10,3) \mathbf{0+}(20,-5)
  \mathbf{00}{*{P}}
\end{verbatim}

will typeset

\begin{center}
\begin{tabular}{|c|c|}
\hline
$P$ & $P$ \\
\hline
\end{tabular}
\end{center}

\textbf{Exercise 9:} How would you change the above to connect the points as shown below?

\begin{center}
\begin{tabular}{|c|c|}
\hline
$P$ & $P$ \\
\hline
\end{tabular}
\end{center}

3n. It is possible to save various things under an (id)entifier with the \texttt{\ldots"(id)"} operations such that it may later be restored using the "(id)" (coord) form.

The simplest form, \texttt{\ldots"(id)"} just saves $c$, making "(id)" set $c$ and thus behave like a coordinate.

The second form, \texttt{\ldots":"(id)"}, makes "(id)" restore the current base without touching $c$.

4 \hspace{1em} \textbf{Objects}

Objects are the entities that are manipulated with the * and ** (pos) operations above to actually get some output in \texttt{X}i-pictures. As for (pos)itions the operations are interpreted strictly from left to right, however, the actual object is built before all the ( modifier)s take effect. The syntax of objects is given in figure 3 with references to the notes below.

\textbf{To Do:} Explain how strange \texttt{TiX} error messages (first of all \texttt{box expected}) can result from incomplete (object) specifications.

\textbf{Notes}

4a. A default (object) is build by using \texttt{\objectbox}

\begin{verbatim}
\{<text>\}
\end{verbatim}

\texttt{\objectbox} is defined equivalent to

\begin{verbatim}
\def\objectbox#1{%
  \hbox{$\textstyle#1$}}
\end{verbatim}

but may be redefined by options or the user. The (text) should thus be in the mode required by the \texttt{objectbox} command—with the default \texttt{objectbox} it should be in math mode.

4b. An (object) built from a \texttt{TiX} box with dimensions $w \times (h + d)$ will have $L_e = R_e = w/2$, $H_e = D_e = (h + d)/2$, thus initially be equipped with the adjustment !c (see note 4f). In particular, in order to get the reference point on the (center of) the base line of the original (\texttt{TiX} box) then you should use the (modifier) !c to get the reference point identical to the \texttt{TiX} reference point use the modifier !c!L.

\texttt{TiX}nical remark: Any macro that expands to something that starts with a (box) may be used as a \texttt{\objectbox} here.

4c. Takes an object and constructs it, building a box; it is then processed according to the proceeding modifiers. This form makes it possible to use any (object) as a \texttt{TiX} box (even outside of \texttt{X}i-pictures) because a finished object is always also a box.

4d. Several (object)s can be combined into a single object using the special command \texttt{\composite} with a list of the desired objects separated with *s as the argument. The resulting box (and object) is the least rectangle enclosing all the included objects.

4e. Take an entire \texttt{X}i-picture and wrap it up as a box as described in §2.1. Makes nesting of \texttt{X}i-pictures possible: the inner picture will have its own zero point which will be its reference point in the outer picture when it is placed there.
```latex

</tbody>
</table>
```

Figure 3: ⟨object⟩s.
4f. An object is shifted a (vector) by moving the point inside it which will be used as the reference point. This effectively pushes the object the same amount in the opposite direction.

**Exercise 10:** What is the difference between the \(0\{a\}+\)DR and \(0\{a\}!\)DR\{a\}? 

4g. A (size) is a pair \(<W, H>\) of the width and height of a rectangle. When given as a (vector) these are just the vector coordinates, i.e., the (vector) starts in the lower left corner and ends in the upper right corner. The possible \((\text{add op})\)erations that can be performed are described in the following table.

<table>
<thead>
<tr>
<th>(\text{add op} )</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>grow</td>
</tr>
<tr>
<td>-</td>
<td>shrink</td>
</tr>
<tr>
<td>=</td>
<td>set to</td>
</tr>
<tr>
<td>+=</td>
<td>grow to at least</td>
</tr>
<tr>
<td>-=</td>
<td>shrink to at most</td>
</tr>
</tbody>
</table>

In each case the (vector) may be omitted which invokes the “default size” for the particular (add op):

<table>
<thead>
<tr>
<th>(\text{add op} )</th>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>++(&lt;2 \times \text{objectmargin})</td>
</tr>
<tr>
<td>-</td>
<td>--(&lt;2 \times \text{objectmargin})</td>
</tr>
<tr>
<td>=</td>
<td>=(&lt;\text{objectwidth}, \text{objectheight})</td>
</tr>
<tr>
<td>+=</td>
<td>+=(&lt;\max(L_c + R_c, D_c + U_c))</td>
</tr>
<tr>
<td>-=</td>
<td>-=(&lt;\min(L_c + R_c, D_c + U_c))</td>
</tr>
</tbody>
</table>

The defaults for the first three are set with the commands

\[
\text{\textbackslash objectmargin \{add op\} \{dimen\}} \\
\text{\textbackslash objectwidth \{add op\} \{dimen\}} \\
\text{\textbackslash objectheight \{add op\} \{dimen\}}
\]

where (add op) is interpreted in the same way as above.

The defaults for +=/-= are such that the resulting object will be the smallest containing/largest contained square.

**Exercise 11:** How are the objects typeset by the \(\text{\textbackslash \times} 0\{a\}\{\sum\}\) and \(\text{\textbackslash \times} 0\{a\}\{\sum\}\) enlarged?

**Bug:** Currently changing the size of a circular object is buggy—it is changed as if it is a rectangle and then the change to the \(R\) parameter affects the circle. This should be fixed probably by a generalisation of the \(\circ\) shape to be ovals or ellipses with horizontal/vertical axes.

4h. An invisible object will be treated completely normal except that it won’t be typeset, i.e., \(\text{X}-\text{pic}\) will behave as if it was.

4i. A hidden object will be typeset but hidden from \(\text{X}-\text{pic}\) in that it won’t affect the size of the entire picture as discussed in \(\S 2.1\).

4j. Setting the \(\text{shape}\) of an object forces the shape of its edge to be as indicated: the kernel just provides the two shapes \([\square]\) and \([\circ]\) corresponding to the outlines

\[
\begin{array}{ccc}
U & X & R \\
L & \times & D
\end{array}
\]

where the \(\times\) denotes the point of the reference position in the object. Extensions can provide more shapes, however, all shapes set the extent dimensions \(L, R, D,\) and \(U\).

The default shape is \([\square]\), i.e., a rectangle.

**Note:** Extensions may add \(\text{shape}\) object \(\text{\textbackslash (modifier)}\) of two kinds: either \([\text{\textbackslash \{keyword\}}\] or \([\text{\textbackslash \{character\}\{argument\}}]\). Some of these \(\text{shape}\)s do other things than set the edge of the object.

4k. Setting the current direction is simply pretending for the typesetting of the object (and the following \(\text{\textbackslash (modifier)}\))s that some connection set it.

It is particularly easy to set \(\text{\textbackslash (diagonal) directions:}

\[
\begin{array}{cccc}
ul = 1u & ur = ru \\
l & c & r \\
d = 1d & dr = rd
\end{array}
\]

Alternatively \(v\text{(vector)}\) sets the direction as if the connection from \(0\) to the \(v\text{(vector)}\) had been typeset except that the \(\text{origin}\) is assumed zero such that directions \(v(x, y)\) mean the natural thing, i.e., is the direction of the connection from \((0, 0)\) to \((x, y)\). With the initial coordinate system this means that the directions \(ur\) and \(v(1, 1)\) are identical.

**Exercise 12:** What is the effect of the \(\text{\textbackslash (modifier)}\)s \(v/1\text{pc}/\) and \(v/-1\text{pc}/\)?

4l. Once the initial direction is established as either the last one or an absolute one then the remainder of the direction is interpreted.
Adding _ and ^ denote the result of rotating the default direction a right angle in the positive and negative direction.

A trailing :((x,y)) is like v((x,y)) but uses the set up (direction) as the base with the such that (1,0) is oriented in \( (x,y) \) and (0,1) oriented in the \( ^ \) direction. Hence a trailing _ is equivalent to :((0,-1)).

5 Decorations

(Decor)ations are actual \TeX\ macros that decorate the current picture in manners that depend on the state. They are used after the \pos\ition either of the outer \texttt{\textbackslash xy...\textbackslash endxy} or inside \{...\}. The possibilities are given in figure 4 with notes below.

Most options add to the available \texttt{(decor)}, in particular the \texttt{v2} option loads many more since \Xy-pic versions prior to 2.7 provided most features as \texttt{(decor)}.

Notes

5a. Saving and restoring allows 'excursions' where lots of things are added to the picture without affecting the resulting \Xy-pic state, \i.e., c, p, and base, and without requiring matching \{\}s. The independence of \{\} is particularly useful in conjunction with the \texttt{\afterPOS} command, for example, the definition

\begin{verbatim}
\def\ToPOS{\save\afterPOS{% \POS**{}??\dir2{}??\dir2{}\restore};p,}
\end{verbatim}

will make the code \texttt{\ToPOS (pos)} make a double arrow from the current object to the \texttt{(pos)} (computed relative to it) such that \texttt{\xy f\texttt{(A)}} \texttt{\ToPOS +\texttt{<1mm,2mm> \textbackslash endxy}} will typeset the picture \begin{center}
\begin{xy}
\diagram{}\end{xy}
\end{center}

\textbf{Note:} Saving this way in fact uses the same state as the \{ \} 'grouping', so the code \texttt{p1, \texttt{p2\textbackslash save}}, \texttt{... \texttt{restore}} will have \texttt{c = p1} both at the \texttt{...} and at the end!

5b. One very tempting kind of \TeX\ commands to perform as \texttt{(decor)} is arithmetic operations on the \Xy-pic state. This will work in simple \Xy-pictures as described here but be warned: \textit{it is not portable} because all \Xy-pic execution is indirect, and this is used by several options in nontrivial ways. Check the \TeX-nical documentation \[5\] for details about this!

Macros that expand to \texttt{(decor)} will always do the same, though.

5c. \texttt{\xyverbose} will switch on a tracing of all the \Xy-pic commands executed. \texttt{\xytracing} traces even more: the entire \Xy-pic state is printed after each modification. \texttt{\xyquiet} restores default quiet operation.

5d. Ignoring means that the \texttt{(pos) (decor)} is still parsed the usual way but nothing is typeset and the \Xy-pic state is not changed.

5e. It is possible to save the commands to generate parts of an \Xy-picture to a file such that subsequent typesetting of those parts is significantly faster: this is called \textit{compiling}. The created file will be named \texttt{(name).\texttt{\textbackslash yxc}} and contain code to check that the compiled code still corresponds to the \texttt{(pos) (decor)} as well as more efficient compiled code to redo it. If the \texttt{(pos) (decor)} has changed then the compilation is redone and \texttt{(name).\texttt{\textbackslash yxc}} recreated.

\textbf{Bug:} Currently you can only compile matrices (build with the matrix feature) where all entries are empty or start with something that is unexpandable.

6 Kernel object library

In this section we present the \textit{library objects} provided with the kernel language—several options add library objects. They fall into three types: Most of the kernel objects (including all those usually used with \*\* to build connections) are \textit{directionals}, described in \S 6.1. The remaining kernel library objects are \textit{circles} of \S 6.2 and \textit{text} of \S 6.3.

6.1 Directionals

The kernel provides a selection of \textit{directionals}: objects that depend on the current direction. They all take the form

\begin{verbatim}
\dir{\langle dir\rangle}
\end{verbatim}

to typeset a particular \langle \texttt{dir}\rangleectitional object. All have the structure

\begin{verbatim}
\langle dir\rangle \rightarrow \langle variant\rangle\{(main)\}
\end{verbatim}

with \langle variant\rangle being (empty) or one of the characters \begin{verbatim} \_23 \end{verbatim} and \langle main\rangle some mnemonic code.

We will classify the directionals primarily intended for building connections as \textit{connectors} and those primarily intended for placement at connection ends or as markers as \textit{tips}.

Figure 5 shows all the \langle \texttt{dir}\rangleectinals defined by the kernel with notes below; each \langle main\rangle type has a line showing the available \langle variant\rangles. Notice that only some
<table>

<td>compile(^5c) to file ⟨name⟩.xyc</td>
</tr>
</tbody>
</table>

Figure 4: ⟨decor⟩ations.

variants exist for each ⟨dir⟩—when a nonexistent variant of a ⟨dir⟩ is requested then the ⟨empty⟩ variant is used silently. Each is shown in either of the two forms available in each direction as applicable: connecting a ○ to a □ (typeset by **\dir⟨dir⟩) and as a tip at the end of a dotted connection of the same variant (i.e., typeset by the ⟨pos⟩ **\dir⟨variant⟩\{\}. ⇒ *\dir⟨dir⟩).

As a special case an entire ⟨object⟩ is allowed as a ⟨dir⟩ by starting it with a *: \dir∗ is equivalent to \object.

**Notes**

6a. You may use \dir\{\} for a “dummy” directional object (in fact this is used automatically by **\{\}). This is useful for a uniform treatment of connections, e.g., making the ? ⟨pos⟩ able to find a point on the straight line from p to c without actually typesetting anything.

6b. The *plain connectors* group contains basic directions that lend themselves to simple connections.

By default \Xe-pic will typeset horizontal and vertical \dir\{-\} connections using \TeX rules since these take up much less space in the produced DVI files. Unfortunately rules is the feature of the DVI format most commonly handled wrong by DVI drivers. Therefore \Xe-pic provides the commands

\NoRules

\UseRules

that will switch the use of rules for \dir\{-\} off and on. They can be used locally as ⟨decor⟩.

As can be seen by the last two columns, these (and most of the other connectors) also exist in double and triple versions with a 2 or a 3 prepended to the name. For convenience \dir\{=\} and \dir\{\} are synonyms for \dir2\{-\} and \dir2\{\}, respectively; similarly \dir\{==\} is a synonym for \dir2\{--\}.

6c. The group of *plain tips* contains basic objects that are useful as markers and arrowheads making connections, so each is shown at the end of a dotted connection of the appropriate kind.

They may also be used as connectors and will build dotted connections. e.g., **\dir\{\} typesets

\Exercise 13: Typeset the following two +s and a tilted square:

\[ + \]

\Hint: the dash created by \dir\{-\} has the length 5pt.

6d. These tips are combinations of the plain tips provided for convenience (and optimised for efficiency). New ones can be constructed using
Figure 5: Kernel library (dir)ectionals
\composite and by declarations of the form
define \dir{dir} (\composite)

which defines \dir{dir} as the (composite) (see note 4d for the details).

6.2 Circle segments

Circle (object)s are round and typeset a segment of the circle centered at the reference point. The syntax of circles is described in figure 6 with explanations below.

The default is to generate a full circle with the specified radius, e.g.,

\xy*\cir<4pt>{}/endxy
typesets "\"
\xy*{H}*\cir{}/endxy — "\$

All the other circle segments are subsets of this and have the shape that the full circle outlines.

Partial circle segments with (orient)ation are the part of the full circle that starts with a tangent vector in the direction of the first (diag)onal (see note 4k) and ends with a tangent vector in the direction of the other (diag)onal after a clockwise (for \_ or anticlockwise (for \*) turn, e.g.,

\xy*\cir<4pt>{\ast\r}\endxy
typesets "\$
\xy*\cir<4pt>{\ast\r}\endxy — "\$
\xy*\cir<4pt>{\ast\u}\endxy — "\$
\xy*\cir<4pt>{d_{\ast}\u}\endxy — "\$
\xy*+(M)*\cir{dr_{\ast}\u}\endxy — "(M)

If the same (diag) is given twice then nothing is typeset, e.g.,

\xy*\cir<4pt>{u*}\endxy
typesets "\$

Special care is taken to setup the (diag)onal defaults:

- After \_ the default is the diagonal 90° anticlockwise from the one before the \_.
- After \* the default is the diagonal 90° clockwise from the one before the \_.

The (diag) before \* or \_ is required for \cir (objects).

Exercise 14: Typeset the following shaded circle with radius 5pt:

\xy*\cir<4pt>{}/endxy

6.3 Text

Text in pictures is supported through the (object) construction

\txt (width) (style) (text)

that builds an object containing (text) typeset to (width) using (style); in (text) \ \ can be used as an explicit line break; all lines will be centered. (style) should either be a font command or some other stuff to do for each line of the (text) and (width) should be either \langle\langle\dimen\rangle\rangle or (empty).

7 Xy-pic option interface

\Xy-pic is provided with a growing number of options supporting specialised drawing tasks as well as exotic output devices with special graphic features. These should all be loaded using this uniform interface in order to ensure that the \Xy-pic environment is properly set up while reading the option.

\xyoption { (option) }
\xyrequire { (option) }

\xyoption will load the \Xy-pic option file xy(option).tex; \xyrequire will do so only if it is not already loaded, if it is then nothing happens.

Sometimes some declarations of an option or header file or whatever only makes sense after some particular other option is loaded. In that case the code should be wrapped in the special command

\xywithoption { (option) } { (code) }

which indicates that if the (option) is already loaded then (code) should be executed now, otherwise it should be saved and if (option) ever gets loaded then (code) should be executed afterwards.

Finally a description of the format of option files: they must look like

Part II

Extensions

This part documents the graphic capabilities added by each standard extension option. For each is indicated the described version number, the author, and how it is loaded.

8 Curve and Spline extension

Vers. 2.9 by Ross Moore (ross@mpee.mq.edu.au)
Load as: \texttt{xyoption[curve]}

This option provides \texttt{Xy-pic} with the ability to typeset spline curves and to construct curved connections using arbitrary directional objects. Warning: Using curves can be quite a strain on \TeX's memory and you should therefore limit the length of curve used on any single page (the memory use is less when combined with a backend with curves build in, \textit{e.g.}, the \texttt{POSTSCRIPT} backend).

The simplest way to specify an \texttt{Xy-pic} curved connection is as the \texttt{decoration} \texttt{\curve{[poslist]}} in which \texttt{[poslist]} is a list of valid \texttt{\pos}itions. As usual, the current \texttt{p} and \texttt{c} are used as the start and finish of the curve, respectively. Within \texttt{[poslist]} the \texttt{\pos}itions are separated by \texttt{&}.

If \texttt{[poslist]} is empty a straight connection is computed. When the length of \texttt{[poslist]} is one or two then the curve is uniquely determined as a single-segment Bézier quadratic or cubic spline. The tangents at \texttt{p} and \texttt{c} are along the lines connecting with the adjacent control point. With three or more \texttt{\pos}itions a cubic B-spline construction is used. Bézier cubic segments are calculated from the given control points.

The curves in the following picture

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{curve_example}
\caption{Example of \texttt{\curve{}} usage.}
\end{figure}

\begin{verbatim}
\def\xy{\texttt{xy}}
\def\curve{\texttt{\curve{}}}
\def\poslist{\texttt{[30,30]}}
\def\args{\texttt{(0,20)\&(40,40)}\texttt{\&(50,-20)\&(60,-10)}}
\end{verbatim}

\begin{verbatim}
\xy \poslist\args \curve\{\args\}
\end{verbatim}

\begin{verbatim}
\endxy
\end{verbatim}

were typeset using:

\begin{verbatim}
\xy (0,20)**{A};(60,0)**{B}
\curve{}
\curve(30,30)\}
\curve(20,40)&(40,40)\}
\curve(10,20)&(30,20)&(50,-20)&(60,-10)\}
\end{verbatim}
except the labels which denote the number of entries in the \textit{poslist} (extending this code to include the labels is set below as an exercise).

The \textit{?}-operator of §3 (note 3g) finds arbitrary \langle place$s\rangle along a curve in the usual way.

\textbf{Exercise 15:} Extend the code given for the curves in the previous picture so as to add the labels giving the number of control points.

Using \textit{?} will set the current direction to be tangential at that \langle place\rangle, and one can \langle slide\rangle specified distances along the curve from a found \langle place\rangle using the \texttt{?.../\langle dimen\rangle/} notation:

\begin{center}
\begin{tikzpicture}
\fill (0,0) circle (0.1);
\draw (0,0) .. controls (0.5,0.5) and (1,0) .. (1.5,-0.5);
\node at (0,0) {$A$};
\node at (1.5,-0.5) {$B$};
\end{tikzpicture}
\end{center}

\textbf{Exercise 16:} Suggest code to produce something like the above picture; the spline curve is the same as in the previous picture. \textit{Hints:} The line is 140pt long and touches 0.28 of the way from $A$ to $B$ and the $x$ is 0.65 of the way from $A$ to $B$.

The positions in \textit{poslist} specify control points which determine the initial and final directions of the curve—leaving $p$ and arriving at $c$—and how the curve behaves in between, using standard spline constructions. In general, control points need not lie upon the actual curve.

A natural spline parameter varies in the interval $[0, 1]$ monotonically along the curve from $p$ to $c$. This is used to specify \langle place$s\rangle along the curve, however there is no easy relation to arc-length. Generally the parameter varies more rapidly where the curvature is greatest. The following diagram illustrates this effect for a cubic spline of two segments (3 control points).

\textbf{Exercise 17:} Write code to produce a picture such as the one above. (\textit{Hint:} Save the locations of places along the curve for later use with straight connections.)

To have the same \textit{pos} occurring as a multiple control point simply use a delimeter, which leaves the \textit{pos} unchanged. Thus \texttt{\textbackslash curve\{\langle pos\rangle\&} uses a cubic spline, whereas \texttt{\textbackslash curve\{\langle pos\}\}} is quadratic. Repeating the same control point three times in succession results in straight segments to that control point. Using the default styles this is an expensive way to get straight lines, but it allows for extra effects with other styles.

\textbf{Notes}

8a. The "drop" object is set once, then "dropped" many times at appropriately spaced places along the curve. If directional, the direction from $p$ to $c$ is used. Default behaviour is to have tiny dots spaced sufficiently closely as to give the appearance of a smooth curve. Specifying a larger size for the "drop" object is a way of getting a dotted curve (see the example in the next note).

8b. The "connect" object is also dropped at each place along the curve. However, if non-empty, this object uses the tangent direction at each place. This allows a directional object to be specified, whose orientation will always match the tangent. To adjust the spacing of such objects, use an empty "drop" object of non-zero size as shown here:

\begin{verbatim}
\texttt{\begin{verbatim}
\xy (0,0)**{(A)}; (50,-10)**{(B)}
\end{verbatim}}
\texttt{\begin{verbatim}
\texttt{\textbackslash curve\{**<4pt>{.} (10,10)&(20,0)&(40,15)\}}
\texttt{\textbackslash curve\{**<8pt>{.} **!/-5pt/\dir{>}
\texttt{((10,-20)&(40,-15))}}
\end{verbatim}}
\end{verbatim}
\end{verbatim}

When there is no "connect" object then the tangent calculations are not carried out, resulting in a saving of time and memory; this is the default behaviour.

8c. The "drop" and "connect" objects can be specified as many times as desired. Only the last specification of each type will actually have any effect. (This makes it easy to experiment with different styles.)

Figure 7: Syntax for curves.

8d. Complicated diagrams having several spline curves can take quite a long time to process and may use a lot of \TeX’s memory. A convenient device, especially while developing a picture, is to show only the location of the control points or to join the control points with lines, as a stylized approximation to the spline curve. The \curve-option \point{} and \line{} are provided for this purpose. Uppercase versions \point{} and \line{} do the same thing but use any \curve-object\s that may be specified, whereas the lowercase versions use plain defaults: small cross for \point{}, straight line for \line{}. Similarly, \c and \cc set the spline curve using any specified \curve-option\s or as a (default) plain curve.

8e. Use of \point{}, \line{}, etc. is extended to enable both the curve and the control points to be easily shown in the same picture. Mixing upper- and lower-case specifies whether the \curve-option\s are to be applied to the spline curve or the (lines joining) control points. See the examples accompanying the next two notes.

8f. By default the control points are marked with a small cross, specified by *\dir{x}. The “connect” object is ignored completely.

8g. With lines joining control points the default “drop” object is empty, while the “connect” object is \direction{} for simple straight lines. If non-empty the “drop” object is placed at each control point. The “connect” object may be used to specify a fancy line style.

8h. When a stack of \pos\s has been established using the \dir{} and \oplus{} commands, these positions can be used and are appended to the \pos\.

Note: Curves will be accessible to users through a \crv\{dir\} command that makes a curve out of every
9 Frame and Bracket extension

Vers. 2.10 by Kristoffer H. Rose (kris@diku.dk)
Load as: \xyoption{frame}

The \texttt{frame} extension provides a variety of ways to put frames in \texttt{Xe}-pictures.

The frames are \texttt{Xe-pic} \texttt{(object)s} on the form

\begin{verbatim}
\frm(modifiers){(frame)}
\end{verbatim}

to be used in \texttt{(pos)itions}: Dropping a frame with \texttt{*\ldots\frm\ldots{(frame)}} will frame the \texttt{c} object modified by the given modifiers; connecting with \texttt{**\ldots\frm\ldots{(frame)}} will frame the object \texttt{c.p} modified by the given modifiers.

Below we distinguish between ordinary frames and 'brackets'.

9.1 Frames

Figure 8 shows the possible frames and the applicable \texttt{(modifier)s} with reference to the notes below.

Notes

9a. The \texttt{\frm{}} frame is a dummy useful for not putting a frame on something, \textit{e.g.}, in macros that take a \texttt{(frame)} argument.

9b. \textit{Rectangular} frames include \texttt{\frm{..}}, \texttt{\frm{-}}, \texttt{\frm{=}}, \texttt{\frm{-=}}, \texttt{\frm{==}}, and \texttt{\frm{o-}}. They all make rectangular frames that essentially trace the border of a rectangle-shaped object.

The \texttt{(frame)s} \texttt{\frm{-}} and \texttt{\frm{=}} allow an optional \texttt{corner radius} that rounds the corners of the frame with quarter circles of the specified radius. This is not allowed for the other frames—the \texttt{\frm{o-}} frame always gives rounded corners of the same size as the used dashes (when \texttt{\xymode} is the default one then these are 5pt in radius).

Exercise 18: How do you think the author typeset the following?

\begin{verbatim}
\begin{xy}
\xymatrix{\text{A} & \text{B}}
\end{xy}
\end{verbatim}

9c. Two frames put just rules in the picture: \texttt{\frm{..}}, puts a shade beneath the (assumed rectangular) object giving the illusion of 'lifting' it; \texttt{\frm<\texttt{(dimen)}\texttt{=}\texttt{..}} makes this shade \texttt{(dimen)} deep. \texttt{\frm{*}} just puts a black rule on top of the object. \texttt{\frm{-}} combines a \texttt{\frm{-}} with a \texttt{\frm{.}}.

9d. Circles done with \texttt{\frm{o}} have radius as \((R+L)/2\) and with \texttt{\frm<\texttt{(dimen)}\texttt{>}\texttt{o}} have radius as the \texttt{(dimen)}; \texttt{\frm<\texttt{oo}}} makes a double circle with the outermost circle being the same as that of \texttt{\frm{o}}.

Exercise 19: What is the difference between \texttt{*\circ{}} and \texttt{**\frm{o}}?

To Do: Allow \texttt{(frame variant)s} like those used for directionals, \textit{i.e.}, \texttt{\frm{2-}} should be the same as \texttt{\frm{=2}}. Add \texttt{\frm{o-}} and more brackets.

9.2 Brackets

The possible brackets are shown in figure 9 with notes below.

Notes

9e. \textit{Braces} are just the standard plain \texttt{TeX} large braces inserted correctly in \texttt{Xe-pic} pictures with the 'nib' aligned with the reference point of the object they brace.

Exercise 20: How do you think the author typeset the following?

\begin{verbatim}
\begin{xy}
\xymatrix{\text{A} & \text{B}}
\end{xy}
\end{verbatim}

9f. \textit{Parenthesis} are like braces except they have no nib and thus do not depend on where the reference point of \texttt{c} is.

Bug: The brackets above requires that the computer modern \texttt{cmex} font is loaded in font position 3.

To Do: Some new frames and several new brackets should be added.

10 Line styles extension

Vers. 2.10 by Ross Moore (roes@mpce.mq.edu.au)
Load as: \xyoption{line}

This extension provides the ability to request various effects related to the appearance of straight lines; \textit{e.g.}, thickness, non-standard dashing, and colour.
Figure 8: Plain (frame)s.

Figure 9: Bracket (frame)s.
These are effects which are not normally available within \TeX. Instead they require a suitable ‘back-end’ option to provide the necessary \texttt{special} commands, or extra fonts, together with appropriate commands to implement the effects. Thus

\begin{itemize}
  \item Using this extension will have no effect on the output unless used with a backend that explicitly supports it.
\end{itemize}

The extension provides special effects that can be used with any \TeX-pic\ object by defining \texttt{[\{shape\}]} modifiers. The modification is local to the (object) currently being built, so will have no effect if this object is never actually used.

The following table lists the modifiers that have so far been defined. They come in two types – either a single keyword, or a key-character with the following text treated as an argument.

<table>
<thead>
<tr>
<th>Modifier</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{[thicker]}</td>
<td>double line thickness</td>
</tr>
<tr>
<td>\texttt{[thinner]}</td>
<td>half line thickness</td>
</tr>
<tr>
<td>\texttt{[{dimen}]}</td>
<td>set thickness to {dimen}</td>
</tr>
<tr>
<td>\texttt{[{word}]}</td>
<td>make {word} set current style settings</td>
</tr>
<tr>
<td>\texttt{[*]}</td>
<td>reuse previous style</td>
</tr>
</tbody>
</table>

Later settings of the linewidth override earlier settings; multiple calls to \texttt{[thicker]} and \texttt{[thinner]} compound.

\textbf{Saving styles} Once specified for an \texttt{[object]}, the collection of styles can be assigned a name, via \texttt{[\{\}]}\{word\}. Then \{word\} becomes a new style, suitable for use with the same or other \texttt{[object]}s. Use a single \{word\} built from ordinary letters. A warning message will be placed in the log file:

\begin{itemize}
  \item \texttt{XY-pic Warning: Defining new style \{word\}}
\end{itemize}

If \{word\} already had meaning the new definition will still be imposed, but the following type of warning will be issued:

\begin{itemize}
  \item \texttt{XY-pic Warning: Redefining style \{word\}}
\end{itemize}

The latter warning will appear if the definition occurs within an \texttt{ymatrix} or \texttt{diagram}. This is perfectly normal, being a consequence of the way that the matrix code is handled. Similarly the message may appear several times if the style definition is made within an \texttt{arrow}.

The following illustrates how to avoid these messages by defining the style without typesetting anything.

\begin{verbatim}
\setbox=\hbox{\texttt{xy\drop [OrangeRed]\{\*A\}}}\end{verbatim}

\textbf{Note 1:} The current colour is regarded as part of the style for this purpose.

\textbf{Note 2:} Such namings are global in scope. They are intended to allow a consistent style to be easily maintained between various pictures and diagrams within the same document.

\section{Rotate and Scale extension}

\textbf{Vers. 2.10 by Ross Moore} (roes@mpce.mq.edu.au)

\textbf{Load as:} \texttt{xyoption\{rotate\}}

This extension provides the ability to request that any object be displayed rotated at any angle as well as scaled in various ways.

These are effects which are not normally available within \TeX. Instead they require a suitable ‘back-end’ option to provide the necessary \texttt{special} commands, or extra fonts, together with appropriate commands to implement the effects. Thus

\begin{itemize}
  \item Using this extension will have no effect on the output unless used with a backend that explicitly supports it.
\end{itemize}

The extension provides special effects that can be used with any \TeX-pic\ object by defining \texttt{[\{shape\}]} modifiers. The modification is local to the (object) currently being built, so will have no effect if this object is never actually used.

The following table lists the modifiers that have so far been defined. They come in two types – either a single keyword, or a key-character with the following text treated as a single argument.

<table>
<thead>
<tr>
<th>Modifier</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{[*]}</td>
<td>align with current direction</td>
</tr>
<tr>
<td>\texttt{[*{direction}]}</td>
<td>align to {direction}</td>
</tr>
<tr>
<td>\texttt{[*{number}]}</td>
<td>rotate {number} degrees</td>
</tr>
<tr>
<td>\texttt{[*{number}]{*{number}}}</td>
<td>scale by {number}</td>
</tr>
<tr>
<td>\texttt{[*{number}]{*{number}}}</td>
<td>scale {x} and {y} separately</td>
</tr>
<tr>
<td>\texttt{[left]}</td>
<td>rotate anticlockwise by 90°</td>
</tr>
<tr>
<td>\texttt{[right]}</td>
<td>rotate clockwise by 90°</td>
</tr>
<tr>
<td>\texttt{[flip]}</td>
<td>rotate by 180°; same as \texttt{[+1,-1]}</td>
</tr>
<tr>
<td>\texttt{[{dsize}]}</td>
<td>scale to double size</td>
</tr>
<tr>
<td>\texttt{[{size}]}</td>
<td>scale to half size</td>
</tr>
</tbody>
</table>

\texttt{[\*]}\texttt{\{shape\}} modifiers specify transformations of the \texttt{[object]} currently being built. If the object has a rectangle edge then the size of the rectangle is transformed to enclose the transformed object; with a circle edge the radius is altered appropriately.

The \texttt{\textbf{NonResizing}} command is also useful to have at the beginning of a document being typeset using a
driver that cannot support scaling effects, in particular when applied to whole diagrams. In any case an
unscaled version will result, but now the spacing and positioning will be appropriate to the unscaled rather
than the scaled size.

Scaling and Scaled Text The \( \texttt{shape} \) modifier can contain either a single scale factor, or a pair indicating
different factors in the \( x \)- and \( y \)-directions. Negative values are allowed, to obtain reflections in the coordinate axes, but not zero.

Rotation and Rotated Text Within \([0\ldots]\) the
\ldots are parsed as a \( \texttt{direction} \) locally, based on the current
direction. The value of count register \texttt{Direction}
contains the information to determine the requested
direction. When no \( \texttt{direction} \) is parsed then \([0\] requests a rotation to align with the current direction.

The special sequence \([0!\ldots]\) is provided to pass
an angle directly to the back-end. The \texttt{Xy-pic} size and shape of the \( \texttt{object} \) with \texttt{rectangleEdge} is un-
changed, even though the printed form may appear ro-
tated. This is a feature that must be implemented spe-
cially by the back-end. For example, using the POST-
SCRIPT back-end, \([0!45]\) will show the object rotated
by 45° inside a box of the size of the unrotated object.

\textbf{To Do}: Provide example of repeated, named trans-
formation.

Reflections Reflections can be specified by a com-
bination of rotation and a flip — either \texttt{hflip} or
\texttt{vflip}.

Shear transformations \textbf{To Do}: Provide the struc-
ture to support these; then implement it in POST-
SCRIPT.

Example The diagram in figure 10 illustrates many
of the effects described above as well as some additional
ones defined by the \texttt{color} and \texttt{rotate} extensions.

Exercise 21: Suggest the code used by the author
to typeset this diagram.

The actual code is given in the solution to the exer-
cise. Use it as a test of the capabilities of your DVI-
driver. The labels should fit snugly inside the accom-
panying rectangles, rotated and flipped appropriately.

\textbf{Bug}: This figure also uses colours, alters line-
thickness and includes some POSTSCRIPT drawing.
The colours may print as shades of gray, with the line
from \( A \) to \( B \) being thicker than normal. The wider
band sloping downwards may have different width and
length according to the DVI-driver used.

12 Colour extension

\textbf{Vers. 2.10 by Ross Moore (ross@mpce.mq.edu.au)}
\textbf{Load as:} \texttt{\%xoption{color}}

This extension provides the ability to request that any
object be displayed in a particular colour.

These are effects which are not normally available
within \texttt{Xy-pic}. Instead they require a suitable ‘back-end’
option to provide the necessary \texttt{\special} commands,
or extra fonts, together with appropriate commands to
implement the effects. Thus

![Using this extension will have no effect on the output unless used with a backend that explicitly supports it.](image)

Colours are specified as a \( \texttt{shape} \) modifier which
gives the name of the colour requested. It is applied
to the whole of the current \( \texttt{object} \) whether this be
text, an \texttt{Xy-pic} line, curve or arrow-tip, or a com-
posite object such as a matrix or the complete picture. How-
ever some DVI drivers may not be able to support the
colour in all of these cases.

\begin{tabular}{ll}
\texttt{\%xycolor(name)} & defines new colour \texttt{\%newcolor(name)\{code\}}
\texttt{\%UseCrayolaColors} & extra colour names
\end{tabular}

If the DVI-driver cannot support colour then a re-
quest for colour only produces a warning message in the
log file. After two such messages subsequent requests
are ignored completely.

Named colours and colour models New colour
names are created with \texttt{\%xycolor}, taking two argu-
ments. Firstly a name for the colour is given, fol-
lowed by the code which will ultimately be passed to
the output device in order to specify the colour. If
the current driver cannot support colour, or grayscale
shading, then the new name will be recognised, but
ignored during typesetting.

For POSTSCRIPT devices, the \texttt{Xy-pic} POSTSCRIPT
dictionary defines operators \texttt{rgb}, \texttt{cmyk} and \texttt{gray}
corresponding to the standard RGB and CMYK colour
models and grayscale shadings. Colours and shades
are described as: \texttt{r g b rgb} or \texttt{c m y k cmyk} or \texttt{s
grey}, where the parameters are numbers in the range
\( 0 \le r, g, b, c, m, y, k, s \le 1 \). The operators link to
the built-in colour models or, in the case of \texttt{cmyk} for
earlier versions of POSTSCRIPT, give a simple emulation
in terms of the RGB model.

\textbf{Saving colour and styles} When styles are saved
using \texttt{\%styles{word}}, see \S 10, then the current colour set-
ting (if any) is saved also. Subsequent use of \texttt{\{word\}}
reverses the colour and accompanying line-style settings.

Further colour names are defined by the command \UseCrystaColours that loads the file \texttt{xyys.col.tex} where more colours are defined (consult the file for the colours and their specifications in the RGB or CMYK models):

\texttt{xyys.col.tex}: This included file (version 2.10) provides definitions for the 68 colours recognised by name by Tomas Rokicki’s \texttt{dvips} driver [4]. These colours become available for use in \texttt{X}pic pictures and diagrams, as \{\texttt{shape}\} modifiers.

The information has been copied from Rokicki’s \texttt{color.pro} POSTSCRIPT prolog file: “There are 68 pre-defined colours, with names taken primarily from the Crayola crayon box of 64 colours” [4, §16.1].

\section*{Part III}
\section*{Features}

This part documents the notation added by each standard feature option. For each is indicated the described version number, the author, and how it is loaded.

\section*{13 All features}

\textbf{Vers. 2.9 by Kristoffer H. Rose (kris@diku.dk)}  
\texttt{Load as: xyoption(all)}

As a special convenience, this feature loads all standard features and extensions, \textit{i.e.}, everything described in this manual except in the ‘backend’ part.

\section*{14 Dummy option}

\textbf{Vers. 2.7 by Kristoffer H. Rose (kris@diku.dk)}  
\texttt{Load as: \xyoption{dummy}}

This option is provided as a template for new options, it provides neither features nor extensions.

\section*{15 Matrix feature}

\textbf{Vers. 2.9 by Kristoffer H. Rose (kris@diku.dk)}  
\texttt{Load as: \xyoption{matrix}}

This option implements "\texttt{X} matrices", \textit{i.e.}, matrices where it is possible to refer to the entry objects by their row/column address. We first describe the general form of \texttt{X} matrices in §15.1, then in §15.2 we summarise the new \{\texttt{coordinate}\} forms used to refer to entries. In §15.3 we explain what parameters can be set to change the spacing and orientation of the matrix, and in §15.4 we explain how the appearance of the entries can be changed.

\subsection*{15.1 \texttt{X} matrices}

The fundamental command of this feature is the \texttt{\xymatrix{...}} that reads a matrix of entries in the generic \texttt{\LaTeX} row&column format, \textit{i.e.}, where rows are separated with \texttt{\\} and contain columns separated with \texttt{&}. Thus a matrix with \texttt{maxrow} rows and \texttt{maxcol} columns where each entry contains \texttt{row}, \texttt{col} is entered as

\begin{verbatim}
\xymatrix{
1,1 \& 1,2 \& \cdots \& 1,\text{maxcol} \\
2,1 \& 2,2 \& \cdots \& 2,\text{maxcol} \\
\vdots \& \ddots \\
\text{maxrow},1 \& \text{maxrow},2 \& \cdots \& \text{maxrow},\text{maxcol}}
\end{verbatim}
(\TeX{}nically the \& character represents any ‘alignment tab’, \textit{i.e.}, character with category code 4).

The points where \texttt{\textbackslash xymatrix} is different from ordinary matrix constructions (like plain \TeX{}'s \texttt{\textbackslash matrix{...}} and \LaTeX{}'s \texttt{array} environment) are:

- arbitrary \TeX{}-pic \textsc{decor}ations may be specified in each entry and will be interpreted in a state where \texttt{\textbackslash c} is the current entry,
- the entire matrix is an object itself with reference point as the top left entry, and
- a progress message “\texttt{\textbackslash xymatrix rowsxcols size}” is printed for each matrix with \texttt{rows} \times \texttt{cols} entries and \TeX{}-pic complexity \texttt{size} (the number of primitive operations performed).

Entries starting with a * are special (described in \S15.4\textsuperscript{5}), so use \{\} to get a *.

For example,

\begin{verbatim}
$$\xy \xymatrix{A & B \[\text{}\] C & D} \end{verbatim}

will typeset

\[
\begin{array}{|c|c|}
  A & B \\
  \hline
  C & D
\end{array}
\]

In fact entries of one matrix may refer to entries of another by using the ⟨pos⟩ save mechanism:

\[
\begin{array}{|c|c|}
  A'' & B' \\
  \hline
  C' & D'
\end{array}
\]

was typeset (using the ‘frame’ extension) by

\begin{verbatim}
$$\xy \xymatrix{A \POS="A" & B\POS="B" \& C\POS="C" & D\POS="D" \} \POS\frm{} \end{verbatim}

\begin{verbatim}
$$\xy \xymatrix{A' \POS;"A"**\dir{.} \& B' \POS;"B"**\dir{.} \& C' \POS;"C"**\dir{.} \& D' \POS;"D"**\dir{.} \} \POS(-10,3) \xymatrix {A' \POS;"A"**\dir{.} \& B' \POS;"B"**\dir{.} \& C' \POS;"C"**\dir{.} \& D' \POS;"D"**\dir{.} \}
\end{verbatim}

\texttt{\textbackslash frm} is the \texttt{\textbackslash pos} new. \texttt{\textbackslash endxy}.

\begin{verbatim}
\POS\frm{}--}
\end{verbatim}

\texttt{\textbackslash endxy}$\$\$\$

\textbf{Bug}: Matrices cannot be nested.

\subsection{New coordinate formats}

it is possible within entries to refer to all the entries of the \TeX{}-matrix using the following special \texttt{\textbackslash coord}inate forms:

\begin{verbatim}
\texttt{\textbackslash r,c} Position and extents of entry in row \texttt{r}, column \texttt{c} (top left is \texttt{"1,1"})
\texttt{[\Delta r,\Delta c]} \texttt{\Delta r} rows below and \texttt{\Delta c} columns right of current entry
\texttt{[\langle hop\rangle]} entry reached by the (hop)s; each (hop) is one of \texttt{\textbackslash d\textbackslash u\textbackslash l\textbackslash r} describing one ‘move’ to a neighbor entry
\end{verbatim}

So the current entry has the synonyms \{\texttt{[0,0]}, \texttt{[]}, \texttt{[rl]}, \texttt{[ud]}, \texttt{[udud]}, etc.

These forms are useful for defining diagrams where the entries are related, \textit{e.g.},

\[
\begin{array}{c}
  A \\
  \hline
  B \\
  \hline
  C \\
\end{array}
\]

was typeset by

\begin{verbatim}
$$\xy \xymatrix{A \POS[];[d]**\dir{.} , \\
  & \text{} \POS[];[d]**\dir{.} \& \text{} \POS[];[d]**\dir{.} \} \end{verbatim}

\end{verbatim}

If an entry outside the \TeX{}-matrix is referenced then an error is reported.

\subsection{Spacing and rotation}

The default spacing distances between rows and columns are called \texttt{r\textbackslash pos} and \texttt{c\textbackslash pos}. They can be changed from the default 2pc by two special commands similar to the ones for the defaults in the kernel:

\begin{verbatim}
\xymatrixrowsep \add \{\texttt{(dimen)}\}
\xymatrixcolsep \add \{\texttt{(dimen)}\}
\end{verbatim}

The spacing around each object can also be changed through modifiers as explained in the following section.

An entire matrix can be rotated by adding a \texttt{rot\textbackslash at\textbackslash ion \texttt{pre\texttt{fix}}} between the \texttt{\xymatrix} command and the opening \texttt{\{}.\texttt{\}}.

\begin{verbatim}
\Theta\texttt{(direction)}
\end{verbatim}

\texttt{\xymatrixrowsep} \texttt{(add \{\texttt{op} \}} \texttt{\{\texttt{(dimen)}\}}

\texttt{\xymatrixcolsep} \texttt{(add \{\texttt{op} \}} \texttt{\{\texttt{(dimen)}\}}

\texttt{\texttt{\textbackslash xymatrixrowsep} \texttt{(add \texttt{op}} \texttt{\{\texttt{\textbackslash dimen}\}}

\texttt{\texttt{\textbackslash xymatrixcolsep} \texttt{(add \texttt{op}} \texttt{\{\texttt{\textbackslash dimen}\}}
This will set the orientation of the rows to \textit{(direction)} (the default corresponds to \texttt{lr}).

\textbf{Note:} Rotation is experimental and the spacing of a rotated matrix may change in future versions.

\begin{exercise}
How did the author typeset the following matrix?
\begin{center}
\begin{tikzpicture}
  \node (A) at (0,0) {$A$};
  \node (B) at (1,-1) {$B$};
  \node (C) at (1,-2) {$C$};
  \node (D) at (1,0) {$D$};

  \draw (A) -- (B);
  \draw (A) -- (C);
  \draw (A) -- (D);
\end{tikzpicture}
\end{center}

\textit{Hint:} It is a $2 \times 2$ matrix and the author used \texttt{\textbackslash entrymodifiers = \{[lo]\}} and \texttt{\textbackslash everyentry = \{\textbackslash drop\textbackslash cir\\}} as explained in the next section.
\end{exercise}

\subsection{Entries}

The object (modifier)s used for the default entries can be changed from the default \texttt{\textbackslash 'C \texttt{=}<object width, object height> +<2 \times object margin>'} (with the effect of centering the object, forcing it to have at least the size \texttt{objectwidth} times \texttt{objectheight} and finally add the \texttt{object margin}) to all sides, by

\begin{verbatim}
\texttt{entrymodifiers = \{ (stuff) \} }
\end{verbatim}

The appearance of a single entry can be modified by entering it as

\begin{verbatim}
\texttt{* (object) (decor)}
\end{verbatim}

This makes the particular entry ignore the entry modifiers and typeset as a kernel object with the same reference point as the (center of) the default object would have had.

\begin{exercise}
Type set the following diagram:
\begin{center}
\begin{tikzpicture}
  \node (A) at (0,0) {$A \times B$};
  \node (B) at (1,0) {$B$};
  \node (C) at (0,-1) {$A$};
  \node (D) at (1,-1) {$B \times A$};

  \draw (A) -- (B) node[above] {$/A$};
  \draw (A) -- (C) node[below] {$/B$};
  \draw (B) -- (D) node[below right] {$\times A$};
  \draw (C) -- (D) node[above left] {$B \times$};
\end{tikzpicture}
\end{center}

Finally, \texttt{\textbackslash everyentry} is used to setup \texttt{(decor)} that should be inserted before everything else in each entry. Initially it is empty but

\begin{verbatim}
\texttt{everyentry = \{ (decor) \}}
\end{verbatim}

will insert \texttt{(decor)} first in each entry. For example,

\begin{verbatim}
\texttt{\textbackslash everyentry = \{\textbackslash drop\textbackslash cir\\}\textbackslash xy\textbackslash matrix{\textbackslash A \textbackslash POS[];[r]**\textbackslash dir{"}\} & B \end{verbatim}

\end{exercise}

\section{Arrow and Path feature}

\textbf{Vers. 2.10 by Kristoffer H. Rose (kris@diku.dk)}

\textbf{Load as:} \texttt{\textbackslash xyoption{arrow}}

This feature provides \texttt{Xy-pic} with the arrow paradigm presented in \cite{6}.

The basic concept introduced is the path: a connection that \texttt{starts} from \texttt{c} (the current object), \texttt{ends} at a specified object, and may be split into several segments between intermediate specified objects that can be individually labelled, change style, have breaks, etc.

\$16.1$ is about the \texttt{\PATH primitive}, including the syntax of paths, and \$16.2$ is about the \texttt{\arrow} customisation of paths to draw arrows using \texttt{Xy-pic} directional objects.

\subsection{Paths}

The fundamental commands of this feature are \texttt{\PATH} and \texttt{\afterPATH} that will parse the \texttt{(path)} according to the grammar in figure \texttt{11} with notes below.

\textbf{Notes}

$16a.$ An \texttt{(action)} can be either of the characters \texttt{=<->}. The associated \texttt{(stuff)} is saved and used to call

\begin{verbatim}
\texttt{\PATH\textbackslash action\{\textbackslash (stuff)\}}
\end{verbatim}

\textit{This name is in conflict with the command of the same name in Karl Berry’s \texttt{plain} format. Fortunately users are unlikely to want both that and \texttt{Xy-pic}.}
at specific times while parsing the ⟨path⟩:

<table>
<thead>
<tr>
<th>⟨action⟩</th>
<th>applied for</th>
</tr>
</thead>
<tbody>
<tr>
<td>=</td>
<td>every segment</td>
</tr>
<tr>
<td>&lt;</td>
<td>next segment</td>
</tr>
<tr>
<td>&gt;</td>
<td>last segment</td>
</tr>
<tr>
<td>-</td>
<td>every subsegment</td>
</tr>
</tbody>
</table>

The =<> actions are always expanded in that sequence after \( p \) and \( c \) have been set up to the proper start and end of the segment but before any ⟨labels⟩ are interpreted, and the = action is expanded for each subsegment after all ⟨labels⟩ have been interpreted (see also note 16d).

The default \PATHaction macro just expands to “\POS ⟨stuff⟩ \relax” thus ⟨stuff⟩ should be of the form ⟨pos⟩ ⟨decor⟩. The user can redefine this—in fact the \arrow command described in §16.2 below is little more than a special \PATHaction command and a clever defaulting mechanism.

16b. Defining default ⟨labels⟩ will insert these first in the label sequence of every ⟨segment⟩. This is useful to draw connections with a ‘center marker’ in particular with arrows, e.g., the ‘mapsto’ example explained below can be changed into a ‘breakto’ example: typing

\begin{verbatim}
\xy**+<0:0>\PATH
-={**{}}
<>{\save?><*}\dir{>}\restore
-={**}\dir{-}
+={**}\dir{}/
'(10,1)**{1} '(20,-2)**{2} (30,0)**{3}
\endxy
\end{verbatim}

will typeset

\begin{verbatim}
0 1 2 3
\end{verbatim}

Note, however, that what goes into “+{…}” is ⟨labels⟩ and thus not a ⟨pos⟩—it is not an action in the sense explained above.
16c. Specifying \{stuff\} will set the “failure continuation” to \{stuff\}. This will be inserted when the last (segment) is expected—it can even replace it or add more (segment)s, i.e.,
\xy \path{=\{\}} \dir{-}\{\}\dir{-}\{2\} (30,0)*\{3\} \dir{-}(1,0)*\{1\}
\endxy
is equivalent to
\xy \path{=\{\}} \dir{-}\{\}\dir{-}\{2\} (30,0)*\{3\} \dir{-}(1,0)*\{1\}
\endxy
typesetting
0 \rightarrow 1 \rightarrow 2 \rightarrow 3
because when \endxy is seen then the parser knows that the next symbol is neither of the characters \'\' and hence that the last (segment) is to be expected. Instead, however, the failure continuation is inserted and parsed, and the (path) is finished by the inserted material.
Failure continuations can be nested:
\xy \path{=\{\}} \dir{-}\{\}\dir{-}\{2\} (30,0)*\{3\} \dir{-}(1,0)*\{1\}
\endxy
will also typeset the connected digits.

16d. A “straight segment” is interpreted as follows:
1. First \(p\) is set to the end object of the previous segment (for the first segment this is \(c\) just before the \path{command}) and \(c\) is set to the (pos) starting the (segment), and the current (slide) is applied.
2. Then the = and < segment actions are expanded (in that sequence) and the \(<\ action is cleared. The resulting \(p\) and \(c\) become the start and end object of the segment.
3. Then all \{labels\} (starting either the \(=\)-defined ones) are interpreted and typeset as described below.
4. Finally the subsegment actions are expanded: If there were \(n\) breaks then there are \(n + 1\) subsegments and thus \path{\{stuff\}} \ will be expanded \(n + 1\) times. The \(i\)th expansion, \(i \in \{1, \ldots, n + 1\}\), will be performed with
\[
p = b_0 \cdot b_{i-1} \\
c = b_{i+1} \cdot b_i
\]
where \(b_i\) denotes break \(i\) except that \(b_0\) is the start and \(b_{n+1}\) the end object of the segment.

Example: Typically \("\) is used to do something that will setup the \(?\{place\}\) format to suit the segment connection which is then used by \"\(<\) to add something to the ‘tail’ of the path and by \"\(>\) to add to its ‘head’, and finally \"\(\sim\) is used to actually typeset the connection between the given breaks. For example,
\xy \path{=\{\}} \dir{-}\{\}\dir{-}\{2\} (30,0)*\{3\} \dir{-}(1,0)*\{1\}
\endxy
will build a ‘mapsto path’
\xy 0 \rightarrow 1 \rightarrow 2 \rightarrow 3
\endxy
as follows: For each segment we do the following: (1) let = typeset an invisible connection that will make? behave correctly; (2) let < make the start point \((p)\) of the first segment be a \path{dir\{\}} on the edge of the original \(p\) (the ;s make us modify \(p\) rather than \(c\)); (3) let > make the end point of the last segment be a \path{dir\{\}} tip; and (4) let \sim typeset each subsegment of the connection as a solid line (that will trace the invisible one set up in (1)).
Numerous variations are possible by varying what goes in which actions, e.g.,
\xy \path{=\{\}} \dir{-}\{\}\dir{-}\{2\} (30,0)*\{3\} \dir{-}(1,0)*\{1\}
\endxy
typesets
0 \rightarrow 1 \rightarrow 2 \rightarrow 3
with every segment a separate mapsto arrow, and
\xy \path{=\{\}} \dir{-}\{\}\dir{-}\{2\} (30,0)*\{3\} \dir{-}(1,0)*\{1\}
\endxy
typesets
0 \rightarrow 1 \rightarrow 2 \rightarrow 3

16e. A turning segment is one that does not go all the way to the given (pos) but only as far as required to make a turn towards it. The \(c\) is set to the actual turn object after a turning segment such that subsequent turning or other segments will start from there, in particular the last segment (which is always straight) can be used to finish a winding line. What the turn looks like is determined by the \{turn\} form:
(empty) Nothing between the ' and the pos is interpreted the same as giving just the (diag) last used out of a turn.

(diag) Specifying a single (diag) d is the same as specifying either of the (cir)cles d' or d,, depending on whether the specified (pos) has its center 'above' or 'below' the line from p in the (diag)onal direction.

(cir) When a full explicit (cir)cle is available then the corresponding (cir)cle object is placed such that its incoming direction is a continuation of a straight connection from p and the outgoing direction points such that a following straight (or last) segment will connect it to c (with the same slide).

Here is an example using all forms of (turn)s:

![Diagram](image)

was typeset by
\xy<4pc,0pc>::(0,0)
**\txt{base}="base"
\PATH="{**{}}"-{{**\dir{-}}}\\ 'l (-1,-1)*{A} "a\\ c (1,-1)*{B} "b\\ '_ul (1,0)*{C} "c\\ "ul"l "base" "d\\ "base" "e
\endxy

**Bug:** Turns are only really reasonable for paths that use straight lines like the one above.

**Note:** Always write a valid (pos) after a (turn), otherwise any following ^ or _ labels can confuse the parser. So if you intend the ^=r in ^=r to be a label then write ^=r, ^=r, using a dummy, (pos)ition.

The default used for turnradius can be set by the operation
\turnradius{add op}{(dimen)}
that works like the kernel \objectmargin command; in fact labelmargin defaults to use objectmargin if not set.

16i. Breaking means to "slice a hole" in the connection and insert (it) there. This is realized by typesetting the connection in question in subsegments, one leading to the break and one continuing after the break as described in notes 16a and 16d.

16j. Unless (it) is a full-fledged (obj)ect (by using the * form), it is typeset using a labelbox object (initially similar to objectbox of basic \Xypic but using \labelstyle for the style).

**Remark:** You can only omit the \s around single letters, digits, and control sequences.

16k. A label is an object like any other in the \Xy picture. Inserting an alias ="(id)" saves the label object as "(id)" for later reference.

**Exercise 26:** Typeset

\label

using (turn)s.

16.2 Arrows

Arrows are paths with a particularly easy syntax for setting up arrows with tail, stem, and head in the style of [6]. This is provided by a single (decor)ation the syntax of which is described in figure 12 (with the added convention that a raised '*' means 0 or more repetitions of the preceding nonterminal).
\begin{table}
\centering
\begin{tabular}{|c|c|}
\hline
Syntax & Action \\
\hline
\arrow\ (arrow) (path) & make (arrow) along (path) \\
\hline
(arrow) & \rightarrow (form)^* \\
\hline
(form) & \rightarrow \emptyset (variant) \\
& \mid \emptyset (variant) \{ (tip) (conn) \} (tip) \} \\
& \mid \emptyset/ \{ (direction) (dist) / \} \\
& \mid \emptyset: \{ \{ (control points) \} \\
& \mid \emptyset \{ (modifier)^* \} \\
& \mid C (anchor) \{ \} \\
& \mid C (anchor) \{ \} \mid @ (anchor) \{ \} \\
\hline
(variant) & \rightarrow (empty) \mid \{ \} \mid \{ \} \mid \{ \} \mid 0 \mid \{ \} \mid 2 \mid 3 \\
\hline
(tip) & \rightarrow (tipchar)^* \\
& \mid \{ \} \\
\hline
(tipchar) & \rightarrow < | > | ( | ) | | | | | | | | | | / \\
& \mid \{ \} \mid \{ \} \mid \{ \} \\
\hline
(conn) & \rightarrow (connchar)^* \\
& \mid \{ \} \\
\hline
(connchar) & \rightarrow \{ \} \mid \{ \} \mid \{ \} \mid \{ \} \\
\hline
\end{tabular}
\caption{\langle arrow\rangle s.}
\end{table}

Notes

161. Building an \langle arrow\rangle is simply using the specified directionals (using \texttt{\dir} of \S 6.1) to build a path: the first \langle tip\rangle becomes the \textit{arrow tail} of the arrow, the \langle conn\ranglection in the middle becomes the \textit{arrow stem}, and the second \langle tip\rangle becomes the \textit{arrow head}. If a \langle variant\rangle is given before the \{ then that variant \texttt{\dir} is used for all three. For example,

\begin{verbatim}
\xy\arrow \emptyset\{-\} (20,7)\endxy
\end{verbatim}
typesets

Exercise 27: Typeset these arrows:

\begin{center}
\begin{tikzpicture}
\node (A) at (0,0) {$A$};
\node (B) at (2,1) {$B$};
\draw (A) -- (B);
\end{tikzpicture}
\end{center}

The above is a flexible scheme when used in conjunction with the kernel \texttt{\newdir} to define all sorts of arrowheads and -tails. For example,

\begin{verbatim}
\newdir{|}{1pt/\dir{|}}
*:1,-.2)\dir{<} \\
*:1,.2)\dir{>}
\end{verbatim}
defines a new arrow tip that makes

\begin{verbatim}
\xy (0,0)**{A} \arrow \emptyset\{-\} (20,3)**{B} \endxy
\end{verbatim}
typeset

\begin{center}
\begin{tikzpicture}
\node (A) at (0,0) {$A$};
\node (B) at (2,1) {$B$};
\draw (A) -- (B);
\end{tikzpicture}
\end{center}

Notice that the fact that the directional uses only \langle tipchar\rangle characters means that it blends naturally with the existing tips.

Exercise 28: Often tips used as ‘tails’ have their ink on the wrong side of the point where they are placed. Fortunately space is also a \langle tipchar\rangle so we can define \texttt{\dir{ ->}} to generate a ‘tail’ arrow. Do this such that

\begin{verbatim}
\xy (0,0)**{A}="a", (20,3)**{B}="b" \arrow \emptyset\{->\} "a";"b" < 2pt> \arrow \emptyset\{ ->\} "a";"b" < -2pt> \endxy
\end{verbatim}
16m. Specifying a \( \text{dir} \) as a \( \text{tip} \) or \( \text{conn} \) means that \( \text{dir}(\text{dir}) \) is used for that \( \text{tip} \) or \( \text{conn} \). For example,
\[
\text{\textbackslash xy\textbackslash arrow \{<\{\}>=\{(20,7)\}\endxy}
\]

16o. The second curve form is the more general one where more than one control point can be defined. The kernel stack is used for this purpose: the control points should be a \( \{\text{pos}\} \) pushing the control points in sequence on the stack: with the sequence \( c_1, \ldots, c_k \) of control \( \{\text{coord}\} \)inates this results in the \{form\}
\[
\{\text{pos} c_1 \ldots c_k\}
\]

See the curve extension described in §8 for the way the control points are used.

Exercise 30: Typeset the ‘balloon arrow’

\[
\text{Hint: it uses a curve with four control points.}
\]

16p. A \( \{\text{pos}{}\{\ldots\}\} \) formation defines what object \( \{\text{modifier}\} \)s should be used when building objects that are part of the arrow. This is mostly useful in conjunction with extensions that define additional \{shape\} modifiers, \( \text{e.g.}, \) if a \{red\} \{modifier\} changes the colour of an object to red then \( \{\text{red}\} \) will make the entire arrow red.

All the features of \{path\}s described above are available for arrows.

17 Two-cell feature

Vers. 2.9 by Ross Moore (ross@mpce.mq.edu.au)
Load as: \texttt{\textbackslash xyoption\texttt{2cell}}

This feature is designed to facilitate the typesetting of curved arrows, either singly or in pairs, together with labels on each part and between. The intended mathematical usage is for typesetting categorical “2-cell” morphisms and “pasting diagrams”, for which special
features are provided. These features also allow attractive non-mathematical effects.

The 2-cell feature makes use of facilities from the ‘curve’ extension which is therefore automatically loaded.

17.1 Typesetting 2-cells in Diagrams

Categorical “2-cell” morphisms are used in the study of tensor categories and elsewhere. The morphisms are displayed as a pair of curved arrows, symmetrically placed, together with an orientation indicated by a short broad arrow, or Arrow. Labels may be placed on all three components.

\[ \begin{array}{c}
  A \xrightarrow{f} B
  \\
  \downarrow g
  \\
  \downarrow h
\end{array} \]

\[ \text{\textbackslash diagram} \]
A\texttt{rtwocell} \texttt{'f,g & B'} \texttt{\textbackslash enddiagram} \]

\[ \begin{array}{c}
  A \xrightarrow{f} B
  \\
  \downarrow a
  \\
  \downarrow b
\end{array} \]

\[ \text{\textbackslash diagram} \]
A\texttt{rupper twocell} \texttt{'f{\alpha}} \texttt{\textbackslash rlower twocell_h{\beta}} \texttt{\textbackslash rto_(.35)g & B'} \texttt{\textbackslash enddiagram} \]

These categorical diagrams frequently having a matrix-like layout, as with commutative diagrams. To facilitate this there are control sequences of the form: \texttt{\textbackslash rtwocell, \textbackslash ultwocell, \textbackslash xtwocell, ...} analogous to the names defined in \texttt{xymatrix}. As this involves the definition of 21 new control sequences, many of which may never be used, these are not defined immediately upon loading \texttt{xy2cell}. Instead the user must first specify \texttt{\textbackslash UseTwocells}.

As in the second example above, just the upper or lower curved arrow may be set using control sequences of the form \texttt{\textbackslash ..uppertwocell} and \texttt{\textbackslash ..lowertwocell}. These together with the \texttt{\textbackslash ..compositemap} family, in which two abutting arrows are set with an empty object at the join, allow for the construction of complicated “pasting diagrams” (see figure 13 for an example).

The following initialise the families of control sequences for use in matrix diagrams.

\begin{verbatim}
\UseTwocells two curves
\UseHalfTwocells one curve
\UseCompositeMaps 2 arrows, end-to-end
\UseAllTwocells  (all the above)
\end{verbatim}

Alternatively 2-cells can be set directly in \textsc{xy}-pictures without using the matrix feature. In this case the above commands are not needed. This is described in \S 17.5.

Furthermore a new directional \texttt{\textbackslash dir{->}} can be used to place an “Arrow” anywhere in a picture, after the direction has been established appropriately. It is used with all of the 2-cell types.

Labels are placed labels on the upper and lower arrows, more correctly ‘anti-clockwise’ and ‘clockwise’, using \texttt{\^} and \texttt{\_}. These are entirely optional with the following token, or grouping, giving the contents of the label. When used with \texttt{\textbackslash ..compositemap} the \texttt{\^} and \texttt{\_} specify labels for the first and second arrows, respectively.

Normally the label is balanced text, set in \TeX’s math mode, with \texttt{\textbackslash twocellstyle} setting the style. The default definition is given by \ldots

\[ \text{\textbackslash def\textbackslash twocellstyle{\scriptstyle style}} \]
This can be altered using \texttt{\textbackslash def} in versions of \TeX or \texttt{\textbackslash redefine} in \E\TeX. However labels are not restricted to being simply text boxes. Any effect obtainable using the \textsc{xy}-pic kernel language can be set within an \texttt{\xybox} and used as a label.

The position of a label can be altered by \texttt{nudging} (see below). Although it is possible to specify multiple labels, only the last usage of each of \texttt{\^} and \texttt{\_} is actually set, previous specifications being ignored.

Similarly a label for the central Arrow must be given, after the other labels, by enclosing it within braces \{\ldots\}. An empty group \{\ldots\} gives an empty label; this is necessary to avoid misinterpretation of subsequent tokens.

17.2 Standard Options

The orientation of the central Arrow may be reversed, turned into an equality, or omitted altogether. In each case a label may still be specified, so in effect the Arrow may be replaced by anything at all.

These effects are specified by the first token in the central label, which thus has the form: \{\{tok\}label\} where \{tok\} may be one of \ldots

\begin{verbatim}
_  Arrow points clockwise
^  Arrow points anti-clockwise
=  no tip, denotes equality
\omit  no Arrow at all
\end{verbatim}

When none of these occurs then the default of \_ is assumed. If the label itself starts with one of these characters then specify \_ explicitly, or enclose the label within a group \{\ldots\}. See \ldots for examples of these, and \textit{Extra Options I}, for more values of \{tok\}.  

31
17.3 Nudging

Positions of all labels may be adjusted, as can the amount of curvature for the curved arrows. The way this is done is by specifying a "nudge" factor (num) at the beginning of the label. Here (num) is a number which specifies the actual position of the label in units of \texttt{\textbackslash xydashl0} (the length of a single dash, normally 5pt) except with \texttt{\textbackslash .compositemap}, see below. Movement is constrained to the perpendicular bisector of the line \texttt{\textbackslash P}. When nudging the label for the central Arrow it is the whole Arrow which is moved, along with its label.

Curvature of the arrows themselves is altered by a nudge of the form \texttt{\textbackslash twocell(num)}. The separation of the arrows, along the bisector, is set to be (num)\texttt{\textbackslash xydashl0}. When (num) is zero, that is \texttt{\textbackslash twocell<0>}, the result is a single straight arrow, its mid-point being the origin for nudging labels. A negative value for (num) is also acceptable; but check the orientation on the Arrow and which of ~ and _ correspond to which component.

The origin for nudging labels is where the arrow crosses the bisector. Positive nudges move the label outwards while negative nudges move towards \texttt{\textbackslash P} and possibly beyond. The default position of a label is on the outside, with edge at the origin.

The origin for nudging the Arrow is at the midpoint of \texttt{\textbackslash P}. A positive nudge moves in the clockwise direction. This will be the direction of the arrowhead, unless it has been reversed using ~.

Labels on a \texttt{\textbackslash .compositemap} are placed relative to the midpoint of the component arrows. Nudges are in units of 1pt. Movement is in the usual \texttt{\textbackslash X-pic} \textit{above} and \textit{below} directions, such that a positive nudge is always outside the triangle formed by the arrows and the line \texttt{\textbackslash P}.

The special nudge value \texttt{\textbackslash ommit} typesets just the Arrow, omitting the curved arrows entirely. When used with labels, the nudge value \texttt{\textbackslash ommit} causes the following label to be ignored.

Exercise 31: Give code to typeset figure 13.

Such code is relatively straight-forward, using "nudging" and \texttt{\textbackslash ommit} to help position the arrows, curves and Arrows. It also uses an \textit{excursion}, as described below in the subsection \textit{Extra Options 3}.

17.4 Extra Options

These features are useful in non-mathematical applications.

1. \texttt{\textbackslash no Arrow}

This is determined by special values for (tok) as the first (or only) character in the central label, as in the above description of the standard options.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'</td>
<td>arrowheads pointing clockwise;</td>
</tr>
<tr>
<td>'</td>
<td>arrowheads pointing anti-clockwise;</td>
</tr>
<tr>
<td>n</td>
<td>arrow tips on both ends;</td>
</tr>
<tr>
<td>!</td>
<td>no tips at all.</td>
</tr>
</tbody>
</table>

The central Arrow is omitted, leaving symmetrically placed curved connections with arrowheads at the specified ends. A label can be placed where the Arrow would have been.

If a special arrowhead is specified using "\texttt{\textbackslash ..}" (see Extra Options 2, below) then this will be used instead of the standard \texttt{\textbackslash dir<>}.
### Syntax: `<two-cell>`

- `\rightarrow (2-cell)(options)(Arrow)`
  - typeset `2-cell` with the `options` and `Arrow`

- `\rightarrow ` two-cell
  - typeset two curved arrows
- `\rightarrow `.uppertwocell
  - typeset upper curved arrow only
- `\rightarrow `.lowertwocell
  - typeset lower curved arrow only
- `\rightarrow `.compositemap
  - use consecutive straight arrows

- `\rightarrow \{ (tok)(text) \}`
  - specifies Arrow orientation and label
- `\rightarrow \{ (nudge)(text) \}`
  - adjust position, use default orientation
- `\rightarrow \{ (text) \}`
  - use default position and orientation

- `\rightarrow ` ±` ± =`
  - oriented anti-/clockwise/equality
- `\rightarrow \text{omit}`
  - no Arrow, default is clockwise
- `\rightarrow ` ±` ± ` `± ` ±`
  - no Arrow; tips on two curved arrows as:
    - anti-/clockwise/double-headed/none

- `\rightarrow ` `(option)`(options)`
  - list of optional modifications

- `\rightarrow ` `(empty)`
  - use defaults
- `\rightarrow ` `(label)`
  - place `(label)` on the upper arrow
- `\rightarrow ` `(label)`
  - place `(label)` on the lower arrow
- `\rightarrow ` `(nudge)`
  - set the curvature, based on `(nudge)` value
- `\rightarrow \text{omit}`
  - do not set the curved arrows
- `\rightarrow ` `(what)` `(object)`
  - place `modmapobject` midway along arrows
  - use `(object)` in place specified by `(what)`

- `\rightarrow ` `(empty)`
  - set curves using the specified `(object)`
- `\rightarrow ` `(object)`
  - use `(object)` with upper/lower curve
- `\rightarrow ` `(object)`
  - use `(object)` for arrow head/tail

---

### Figure 14: `<two-cell>`s

---

### Syntax: `<label>`

- `\rightarrow ` `(text)` | `(nudge)` `(text)`
  - set `(text)` displaced by `(nudge)`

- `\rightarrow ` `<(number)>`
  - positions object along a fixed axis
- `\rightarrow ` `<\text{omit}>`
  - do not typeset the object

---

### Figure 15: nudging and `<label>`s
2. Changing Tips and Module Maps

The following commands are provided for specifying the (object) to be used when typesetting various parts of the twocells.

<table>
<thead>
<tr>
<th>command</th>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>\modmapobject{object}</td>
<td>\dir{}</td>
</tr>
<tr>
<td>\twocellhead{object}</td>
<td>\dir{}</td>
</tr>
<tr>
<td>\twocelltail{object}</td>
<td>\dir{}</td>
</tr>
<tr>
<td>\arrowobject{object}</td>
<td>\dir{=}</td>
</tr>
<tr>
<td>\curveobject{object}</td>
<td>{}</td>
</tr>
<tr>
<td>\uppercurveobject{object}</td>
<td></td>
</tr>
<tr>
<td>\lowercurveobject{object}</td>
<td></td>
</tr>
</tbody>
</table>

These commands set the object to be used for all subsequent 2-cells at the same level of \TeX group. \curveobject specifies both of the upper- and lower-curve objects. For some of these there is also a way to change the object for the current 2-cell only. This requires a "-"(option) which is described below, except for the \curveobject types, which are discussed in \textit{Extra Options 4.}

These effects are specified by placing options after the \twocell control sequence, e.g. \twocelloptions labels... Each option is either a single token (tok), or a "-"(tok) with a single argument: "-{}\{arg\}. Possibilities are listed in the following table, in which {\ldots} denotes the need for an argument.

| \omit                  | no arrows. Arrow and label only;          |
|                       | ! \change module-map indicator;           |
| \ldots                | \change arrow-head to \{..\};             |
| \ldots                | \place \change tail on arrow(s);         |
| \ldots                | \change object used to set curves;       |
| \ldots                | use object \{..\} to set upper curve;    |
| \ldots                | use object \{..\} to set lower curve;    |

Here we discuss the use of !, \ldots and \omit. The description of \ldots, \ldots and \{..\} is given in \textit{Extra Options 4.}

The default module map indicator places a single dash crossing the arrow at right-angles, located roughly midway along the actual printed portion of the arrow, whether curved or straight. This takes into account the sizes of the objects being connected, thereby giving an aesthetic result when these sizes differ markedly. This also works with \compositemap where an indicator is placed on each arrow. The actual object can be changed using \modmapobject.

Any of the standard Xy-pic tips may be used for arrow-heads. This is done using \ldots, for example \ldots\{\dir{}\} gives double-headed arrows. Similarly \ldots\{\ldots\} can be used to place an arrow-tail. Normally the arrow-tail is , so is not placed; but if a non-empty tail has been specified then it will be placed, using \drop. No guarantee is offered for the desired result being obtained when an arrow-tail is mixed with the features of \textit{Extra Options 1.}

3. Excursions

The syntax for the \texttt{x..twocell} types and for \compositemap is a little different to what might be expected from that for \texttt{xto, xline}, etc. For example,

\begin{verbatim}
\twocell[\<\<\(\ldots\)>\>\ldots](\<\<\(\ldots\)>\>\ldots);\ldots
\end{verbatim}

connects to the (pos) displaced by (displace) from the relative cell location specified by (hop). The displacement can be any string of valid Xy-pic commands, but they must be enclosed within a group \ldots. When the cell location is required, a null grouping {}\ldots must be given.

When used with the \texttt{\omit} nudge, such excursions allow a labelled Arrow to be placed anywhere within an Xy-pic diagram; furthermore the Arrow can be oriented to point in any direction.

4. Fancy curves

By specifying \texttt{\curveobject} an arbitrary object may be used to construct the curved arrows. Indeed with a \texttt{\ldots twocell} different objects can be used with the upper and lower curves by specifying \texttt{uppercurveobject} and \texttt{\lowercurveobject}.

These specifications apply to all 2-cells subsequently constructed at the same level of \TeX grouping. Alter-
natively using an \-option, as in \textit{Extra Options} 2, allows such a specification for a single 2-cell or curved part.

Objects used to construct curves can be of two types. Either a single (object) is set once, with copies placed along the curve. Alternatively a directional object can be aligned with the tangent along the curve. In this case use a specification takes the form:
\begin{verbatim}
\texttt{\textbackslash curveobject\{spacer\}**\{(object)\}.}
\end{verbatim}

Here (spacer) may be any (object) of non-zero size. Typically it is empty space, e.g. +\{dimen\}{}.

Exercise 32: Give code to typeset the following diagrams.

egin{center}
\begin{tikzpicture}
  \node at (0,0) {FUN \& gaMES};
\end{tikzpicture}
\end{center}

\begin{center}
\begin{tikzpicture}
  \node at (0,0) {continuous power};
\end{tikzpicture}
\end{center}

\begin{center}
\begin{tikzpicture}
  \node at (0,0) {Ground State NiCd};
  \node at (2,1) {Excited State};
  \node at (2,-1) {pulsed emission};
\end{tikzpicture}
\end{center}

17.5 2-cells in general $\LaTeX$-pictures

Two-cells can also be set directly within any $\LaTeX$-picture, without the matrix feature, using either \texttt{\textbackslash drop} or \texttt{\textbackslash connect}.

\begin{verbatim}
\def\myPOS\{\POS\}\def\goVia\1\%
  \afterPOS\{\textbackslash connect\1\myPOS\}\endverbatim

\begin{verbatim}
\xy\*+\{A\}"A",+\{1 cm,1.5 cm\}++\{B\}"B", 
+\{2.0 cm,0 pt\}++\{C\}"C", 
+\{1 cm,-1.5 cm\}++\{D\}"D", 
"A";\goVia\{\textbackslash uppertwocell\"\alpha{}\}"B{}\} 
;\goVia\{\textbackslash twocell\"\zeta{}_{\chi{}\{\gamma{}\}}\}"C{}\} 
;\goVia\{\textbackslash compositemap\}"D{}\}, 
"A";\goVia\{\textbackslash lowertwocell\}"D{}\} \endxy
\end{verbatim}

The code shown is a compact way to place a chain of 2-cells within a picture. It illustrates a standard technique for using \texttt{\afterPOS} to find a (pos) to be used for part of a picture, then subsequently reuse it. Also it is possible to use \texttt{\drop} or \texttt{\decor} to specify the 2-cells, giving the same picture.

18 Version 2 Compatibility feature

\textbf{Vers. 2.10 by Kristoffer H. Rose (kris@diku.dk) Load as: $\texttt{\\textbackslash extstyle}$}

This option provides backwards compatibility with $\LaTeX$-pic version 2: diagrams written according to the "Typesetting diagrams with $\LaTeX$-pic: User’s Manual" [7] should typeset correctly with this option loaded.

There are a few exceptions: the features described in §18.1 below are not provided because they are not as useful as the author originally thought and thus virtually never used. And one extra command is provided to speed up typesetting of documents with $\LaTeX$-pic version 2 diagrams by allowing the new compilation functionality on old diagrams.

The remaining sections list all the obsolete commands and suggest ways to achieve the same things using $\LaTeX$-pic 2.10, i.e., without the use of this option. They are grouped as to what part of $\LaTeX$-pic replaces them; the compilation command is described last.

\textbf{Note:} "version 2" is meant to cover all public releases of $\LaTeX$-pic in 1991 and 1992, i.e., version 1.40 and versions 2.1 through 2.6. The published manual cited above (for version 2.6) is the reference in case of variations between these versions, and only things documented in that manual will be supported by this option!

18.1 Unsupported incompatibilities

Here is a list of known incompatibilities with version 2 even when the v2 option is loaded.

- Automatic 'shortening' of arrow tails by $\texttt{\\textbackslash break}$ was a bug and has been 'fixed' so it does not work any more. Put a $\texttt{\\textbackslash hole}$ break before it.
- The version 2.6 * position break is not available. Use the : and :: operators.

35
• Using \( t_1; t_2: (x, y) \) as the target of an arrow command does not work. Enclose it in braces, \( i.e. \), write

\[ \{ t_1; t_2: (x, y) \} \]

• The older \texttt{\textbackslash{}pit}, \texttt{\textbackslash{}apit}, and \texttt{\textbackslash{}bpit} commands are not defined. Use \texttt{\textbackslash{}dir\{}\texttt{\textbackslash{}text}} (or \texttt{\textbackslash{}tip}) with variants and rotation.

If you do not use these features then your version 2 (and earlier) diagrams should typeset the same with this option loaded except that sometimes the spacing with version 2.10 is slightly different from that of version 2.6 which had some spacing bugs.

### 18.2 Obsolete kernel features

The following things are added to the kernel by this option and described here: idioms, obsolete positions, obsolete connections, and obsolete objects. For each we show the suggested way of doing the same thing without this option:

**Removed \texttt{\textbackslash{}ams\text{-}\texttt{\textbackslash{}tex}} idioms**

Some idioms from \texttt{\textbackslash{}ams\text{-}\texttt{\textbackslash{}tex}} are no longer used by \texttt{\textbackslash{}amsthm}: the definition commands \texttt{\textbackslash{}define} and \texttt{\textbackslash{}redefine}, and the size commands \texttt{\textbackslash{}dsizer}, \texttt{\textbackslash{}sizer}, \texttt{\textbackslash{}ssizer}, and \texttt{\textbackslash{}ssssizer}. Please use the commands recommended for your format—for plain \texttt{\textbackslash{}tex} these are \texttt{\textbackslash{}def} for the first two and \texttt{\textbackslash{}displaystyle, \textbackslash{}textstyle, \textbackslash{}scripts, \textbackslash{}scriptstyle} for the rest. The \texttt{v2} option ensures that they are available anyway.

Version also 2 used the \texttt{\textbackslash{}ams\text{-}\texttt{\textbackslash{}tex}} \texttt{\textbackslash{}text} and a (non-object) box construction \texttt{\textbackslash{}text} which are emulated—\texttt{\textbackslash{}text} is only defined if not already defined, however, using the native one (of \texttt{\textbackslash{}ams\text{-}\textbackslash{}tex} or \texttt{\textbackslash{}ams\text{-}\textbackslash{}etex} or whatever) if possible. Please use the \texttt{\textbackslash{}text} object construction directly since it is more general and much more efficient!

**Obsolete state**

In version 2 the available state dimensions had different names: \texttt{\textbackslash{}cL, \textbackslash{}cR, \textbackslash{}cH}, and \texttt{\textbackslash{}CD} for \texttt{\textbackslash{}Lc, \textbackslash{}Rc, \textbackslash{}Uc}, and \texttt{\textbackslash{}Dc}. These are made synonyms for the new names.

**Obsolete position manipulation**

In version 2 many things were done using individual \texttt{\textbackslash{}decor} control sequences that are now done using \texttt{\textbackslash{}pos} operators.

---

<table>
<thead>
<tr>
<th>Version 2 positioning</th>
<th>Replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{\textbackslash{}go{}\texttt{\textbackslash{}pos}}</td>
<td>\texttt{\textbackslash{}POS{}\texttt{\textbackslash{}pos}}</td>
</tr>
<tr>
<td>\texttt{\textbackslash{}aftergo{}\texttt{\textbackslash{}decor}} \texttt{\textbackslash{}pos}}</td>
<td>\texttt{\textbackslash{}after{}\texttt{\textbackslash{}decor}} \texttt{\textbackslash{}pos}}</td>
</tr>
</tbody>
</table>

Obsolete connections

These connections are now implemented using directionals.

<table>
<thead>
<tr>
<th>Version 2 connection</th>
<th>Replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{\textbackslash{}none}</td>
<td>\texttt{\textbackslash{}connect \textbackslash{}dir{}\texttt{\textbackslash{}pos}}</td>
</tr>
<tr>
<td>\texttt{\textbackslash{}solid}</td>
<td>\texttt{\textbackslash{}connect \textbackslash{}dir{}\texttt{\textbackslash{}pos}}</td>
</tr>
<tr>
<td>\texttt{\textbackslash{}dashed}</td>
<td>\texttt{\textbackslash{}connect \textbackslash{}dir{}\texttt{\textbackslash{}pos}}</td>
</tr>
<tr>
<td>\texttt{\textbackslash{}dotted}</td>
<td>\texttt{\textbackslash{}connect \textbackslash{}dir{}\texttt{\textbackslash{}pos}}</td>
</tr>
<tr>
<td>\texttt{\textbackslash{}dottedwith{}\texttt{\textbackslash{}text}}</td>
<td>\texttt{\textbackslash{}connect \textbackslash{}dir{}\texttt{\textbackslash{}text}}</td>
</tr>
</tbody>
</table>

Note how the ‘hidden’ specifier \texttt{\textbackslash{}h} should be used because version 2 connections did not affect the size of diagrams.

**Obsolete objects**

These objects all have \texttt{\textbackslash{}dir\{-\}} names now:

<table>
<thead>
<tr>
<th>Version 2</th>
<th>Replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{\textbackslash{}notip}</td>
<td>\texttt{\textbackslash{}dir{}\texttt{\textbackslash{}pos}}</td>
</tr>
<tr>
<td>\texttt{\textbackslash{}stop}</td>
<td>\texttt{\textbackslash{}dir{}\texttt{\textbackslash{}pos}}</td>
</tr>
<tr>
<td>\texttt{\textbackslash{}astop}</td>
<td>\texttt{\textbackslash{}dir{}\texttt{\textbackslash{}pos}}</td>
</tr>
<tr>
<td>\texttt{\textbackslash{}bstop}</td>
<td>\texttt{\textbackslash{}dir{}\texttt{\textbackslash{}pos}}</td>
</tr>
<tr>
<td>\texttt{\textbackslash{}tip}</td>
<td>\texttt{\textbackslash{}dir{}\texttt{\textbackslash{}pos}}</td>
</tr>
<tr>
<td>\texttt{\textbackslash{}bstop}</td>
<td>\texttt{\textbackslash{}dir{}\texttt{\textbackslash{}pos}}</td>
</tr>
<tr>
<td>\texttt{\textbackslash{}atip}</td>
<td>\texttt{\textbackslash{}dir{}\texttt{\textbackslash{}pos}}</td>
</tr>
<tr>
<td>\texttt{\textbackslash{}btip}</td>
<td>\texttt{\textbackslash{}dir{}\texttt{\textbackslash{}pos}}</td>
</tr>
<tr>
<td>\texttt{\textbackslash{}atip}</td>
<td>\texttt{\textbackslash{}dir{}\texttt{\textbackslash{}pos}}</td>
</tr>
<tr>
<td>\texttt{\textbackslash{}btip}</td>
<td>\texttt{\textbackslash{}dir{}\texttt{\textbackslash{}pos}}</td>
</tr>
<tr>
<td>\texttt{\textbackslash{}ahook}</td>
<td>\texttt{\textbackslash{}dir{}\texttt{\textbackslash{}pos}}</td>
</tr>
<tr>
<td>\texttt{\textbackslash{}bhook}</td>
<td>\texttt{\textbackslash{}dir{}\texttt{\textbackslash{}pos}}</td>
</tr>
<tr>
<td>\texttt{\textbackslash{}aturn}</td>
<td>\texttt{\textbackslash{}dir{}\texttt{\textbackslash{}pos}}</td>
</tr>
<tr>
<td>\texttt{\textbackslash{}bturn}</td>
<td>\texttt{\textbackslash{}dir{}\texttt{\textbackslash{}pos}}</td>
</tr>
</tbody>
</table>

The older commands \texttt{\textbackslash{}pit}, \texttt{\textbackslash{}apit}, and \texttt{\textbackslash{}bpit}, are not provided.
### 18.3 Obsolete extensions

#### Frames

The version 2 frame commands are emulated using the frame extension (as well as the \dotframed, \dashframed, and \rounddashframed commands communicated to some users by electronic mail):

<table>
<thead>
<tr>
<th>Version 2 object</th>
<th>Replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td>\framed</td>
<td>\drop\frm{-}</td>
</tr>
<tr>
<td>\framed{&lt;dimen&gt;}</td>
<td>\drop\frm{&lt;dimen&gt;}{-}</td>
</tr>
<tr>
<td>\framed</td>
<td>\drop\frm{-}</td>
</tr>
<tr>
<td>\framed{&lt;dimen&gt;}</td>
<td>\drop\frm{&lt;dimen&gt;}{-}</td>
</tr>
<tr>
<td>\dotframed</td>
<td>\drop\frm{-}</td>
</tr>
<tr>
<td>\dashframed</td>
<td>\drop\frm{-}</td>
</tr>
<tr>
<td>\rounddashframed</td>
<td>\drop\frm{-}</td>
</tr>
</tbody>
</table>

### 18.4 Obsolete features

Version 2 had commutative diagram functionality corresponding to parts of the matrix and arrow features. These are therefore loaded and some extra definitions added to emulate commands that have disappeared.

#### Matrices

The \diagram (rows) \enddiagram command is provided as an alias for \xymatrix (rows). \endxy centered in math mode and \LaTeX\ diagrams changes it to use \begin{...} \end{...} syntax. v2 sets a special internal `old matrix' flag such that trailing \\ are ignored and entries starting with * are safe.

NoisyDiagrams is ignored because the matrix feature always outputs progress messages.

Finally the version 2 \spreaddiagramrows and \spreaddiagramcolumns spacing commands are emulated using \xymatrixrowsep and \xymatrixcolsep.

### 18.5 Obsolete loading

The v2 User's Manual says that you can load \xy\pic with the command \input\xy\pic and as a \TeX\ ‘style option' [\xy\pic]. This is made synonymous with loading this option by the files \xy\pic\tex and \xy\pic.sty distributed with the v2 option.

**xy\pic.doc**  This file (version 2.10) just loads the v2 feature.

**xy\pic.sty**: Loads \xy.sty and the v2 feature.

### 18.6 Compiling v2-diagrams

In order to make it possible to use the new compilation features even on documents written with \xy\pic\ v2, the following command has been added:

\begin{verbatim}
\diagramcompileto{(name)} ... \enddiagram
\end{verbatim}

which is like the ordinary diagram command except the result is compiled into a file (name).\text{.xy}. Note that compilation is not quite safe in all cases!

There is also the following command that switches on automatic compilation of all diagrams created with the v2 \diagram ... \enddiagram command:

\begin{verbatim}
\CompileAllDiagrams{(prefix)}
\end{verbatim}

will apply \xyc\{prefix\}n\{...\} to each diagram with n a sequence number starting from 1.

If for some reason a diagram does not work when compiled then replace the \diagram command with \diagramno\compilation (or in case you are using the \TeX\ form, \begin{diagramno\compilation}), or use

\begin{verbatim}
\NoCompileAllDiagrams
\end{verbatim}

\begin{verbatim}
\ReCompileAllDiagrams
\end{verbatim}

where the last switches compilation back on.
Part IV
Backends

This part describes variant backends that support the customisation of the produced DVI files to particular output devices. For each is indicated the described version number, the author, and how it is loaded.

19 PostScript backend

Vers. 2.10 by Ross Moore (ross@mpce.mq.edu.au)
Load as: \xypic\option{ps}

\Xypic is a ‘back-end’ which provides \Xypic with the ability to produce DVI files that use \PostScript\specials for drawing rather than the \Xypic fonts.

In particular this makes it possible to print \Xypic DVI files on systems which do not have the ability to load the special fonts. The penalty is that the generated DVI files will only function with one particular DVI driver program. Hence whenever \Xypic is activated it will warn the user:

\Xypic Warning: The produced DVI file is not portable: It contains \PostScript\specials for (one particular) driver

A more complete discussion of the pros and cons of using this backend is included below.

19.1 Choosing the DVI-driver

To activate the use of \PostScript the user must specify one of the following command that selects the format of the \specials to be used:

\begin{itemize}
  \item \UsePSspecials \{\{\text{driver}\}\}
  \item \NoPSspecials \quad \text{cancels} \PostScript\specials
  \item \UsePSspecials \quad \text{restores} \PostScript\specials
\end{itemize}

The \UsePSspecials initially causes a special driver file (see below) to be read. This file contains definitions which are specific to the particular \{\text{driver}\}. Note that some drivers may not be able to support all of the \PostScript effects that can be requested from within \Xypic. When an unsupported effect is encountered, it is simply ignored. A message warning that the requested effect is unavailable will be produced unless too many such messages have already been issued.

Use of fonts is restored at any point by calling \NoPSspecials after which use of \PostScript is restored by using \UsePSspecials without need of an argument. This allows \PostScript to be turned on and off for individual diagrams, or for portions of a single diagram. Use of these commands obeys normal \TeX scoping rules, so if \NoPSspecials or \UsePSspecials is specified within an environment, the previous setting will be restored upon leaving that environment.

For users of \LaTeX\$2\varepsilon$, and presumably \LaTeX$3$ (when it becomes available), the driver type will be inherited from any corresponding \PostScript option specified with the \documentclass command, see [1, page 317]. The implicit \UsePSspecials will be executed at the \begin{document} line; hence any \NoPSspecials must occur after this to be effective.

The following table, which mimics the one in the stated \LaTeX\$2\varepsilon$ reference, describes current support for \PostScript drivers: \* denotes full support, for all the features the driver can handle; ? denotes that some features have not been tested, but may still work; - denotes no support as yet. Please note the spelling, which corresponds to the way the respective writers refer to their own products within their own documentation. Alternative combinations of upper- and lowercase letters are not guaranteed to work correctly.

<table>
<thead>
<tr>
<th>(driver)</th>
<th>Description</th>
<th>\Xypic</th>
</tr>
</thead>
<tbody>
<tr>
<td>dvips</td>
<td>Tomas Rokicki’s \texttt{dvips}</td>

<td>Eberhard Matte’s \texttt{em-T\TeX}</td>
<td>-</td>
</tr>
</tbody>
</table>

Other DVI-drivers may already work if they use conventions similar to \texttt{dvips}, \texttt{O2T\TeX} or \texttt{TEXTURES}. The \TeX{}\nical documentation [5] in the file \texttt{xyps.doc} contains instructions concerning how to make \Xypic work with other drivers. To have another driver specifically supported it is only necessary to inform the author of its existence, how it handles \specials, and negotiate with him a means for testing/verifying the implementation.

It should be possible to change \texttt{(driver)} up until such time as a \texttt{special} is actually used. This is to allow users to switch from a system default. This ability is new with version 2.9; any difficulties with this feature should be reported to the author.

The following lists the \texttt{(driver)s} available, including some experimental ones not mentioned above. The associated driver file is given in parentheses, along with any special considerations needed when using them.

\texttt{dvips} for \texttt{dvips} (\texttt{xyps-dvips.tex}): This included file (version 2.10) provides \Xypic support for the \texttt{dvips} driver by Tomas Rokicki [4] (it has been tested with dvips version 5.55a).

\texttt{Textures} for \texttt{TEXTURES} (\texttt{xypts-txt.tex}):

This included file (version 2.10) provides \Xypic
support for the DVI driver of TEXTURES,\textsuperscript{8} for the Macintosh.\textsuperscript{9}

OzTeX for OzTeX (xypic-\texttt{ps}). This included file (version 2.10) provides \texttt{X}P\texttt{S} support for the DVI driver of OzTeX by Andrew Trevorrow.\textsuperscript{10}

\textbf{Bug:} Colour support is not complete (see INSTALL.OzTeX)

\textbf{Note:} To use \texttt{X}P\texttt{S-pic} effectively with OzTeX requires changing several parameters. This is described in the file INSTALL.OzTeX of the \texttt{X}P\texttt{S-pic} distribution.

dv itching for dv itching (xypic-\texttt{dte}.\texttt{tex}): This included file (version 2.10) provides \texttt{X}P\texttt{S} support for the \texttt{dv itching} DVI driver by James Clark.

\textbf{Bug:} This code has not been tested!

dviwindo for dvwindo (xypic-\texttt{dwdte}.\texttt{tex}): This included file (version 2.10) provides \texttt{X}P\texttt{S} support for the \texttt{dvwindo} DVI driver.

\textbf{Bug:} This code has not been tested!

dvi pub for dvipub (xypic-\texttt{pub}.\texttt{tex}): This included file (version 2.10) provides \texttt{X}P\texttt{S} support for the \texttt{dvipub} DVI driver.

\textbf{Bug:} This code has not been tested!

Information to improve the abilities of these drivers should be conveyed to the author. Printed technical documentation or software would be the most useful form, though e-mail concerning good experiences would also be helpful.

19.2 Why use PostScript.

At some sites users have difficulty installing the extra fonts used by \texttt{X}P\texttt{S-pic}. The \texttt{.tfm} files can always be installed locally but it may be necessary for the \texttt{.pk} bitmap fonts (or the \texttt{.mf} METAFONT fonts) to be installed globally, by the system administrator, for printing to work correctly. If PostScript is available then \texttt{X}P\texttt{S} allows this latter step to be bypassed.

\textbf{Note:} with \texttt{X}P\texttt{S} it is still necessary to have the \texttt{.tfm} font metric files correctly installed, as these contain information vital for correct typesetting.

Other advantages obtained from using \texttt{X}P\texttt{S}-ps are the following:

- Circles and circle segments can be set for arbitrary radii.
- Straight lines are straighter and cleaner.
- The range of possible angles of directionals is greatly increased.
- Spline curves are smoother. True dotted and dashed versions are now possible, using equally spaced segments which are themselves curved.
- The PostScript file produced by a driver from an \texttt{X}P\texttt{S} DVI file is in general significantly smaller than one produced by processing an ‘ordinary’ DVI file using the same driver. One reason for this is that no font information for the \texttt{X}P\texttt{S-pic} fonts is required in the PostScript file; this furthermore means that the use of \texttt{X}P\texttt{S-pic} does not in itself limit the PostScript file to a particular resolution.\textsuperscript{11}
- The latest version of \texttt{X}P\texttt{S-pic} now enables special effects such as variable line thickness, gray-level and colour. Also, rotation of text and (portions of) diagrams is now supported with some drivers. Similarly whole diagrams can be scaled up or down to fit a given area on the printed page. Future versions will allow the use of regions filled with colour and/or patterns, as well as other attractive effects.

Some of the above advantages are significant, but they come at a price. Known disadvantages of using \texttt{X}P\texttt{S} include the following:

- A DVI file with specials for a particular PostScript driver can only be previewed if a previewer is available that supports exactly the same \texttt{\special} format. A separate PostScript previewer will usually be required.
- The DVI files created using \texttt{X}P\texttt{S} lose their “device-independence”. So please do not distribute DVI files with PostScript specials—send either the \texttt{T}P\texttt{X} source code, expecting the recipient to have \texttt{X}P\texttt{S-pic} \textsuperscript{12}, or send a (compressed) PostScript file.

\textbf{PostScript header file} With some DVI-drivers it is more efficient to have the PostScript commands that \texttt{X}P\texttt{S}-ps needs loaded initially from a separate “header” file. To use this facility the user has the following commands available…

```latex
\UsePSTrick{}\}
```

\textsuperscript{8}TEXTURES is a product of Blue Sky Research. \texttt{X}P\texttt{S} has been tested on versions 1.3b and later; no guarantee is given for earlier versions.
\textsuperscript{9}Macintosh is a trademark of Apple Computer Inc.
\textsuperscript{10}OzTeX v1.7 is a shareware implementation of \texttt{TP} by Macintosh available from many bulletin boards and ftp sites; v1.5 and earlier versions were freeware. Email contact: (akt150@huxley.anu.edu.au).
\textsuperscript{11}Most \texttt{TP} \texttt{PostScript} drivers store the images of characters used in the text as bitmaps at a particular resolution. This means that the PostScript file can only be printed without loss of quality (due to bitmap scaling) at exactly this resolution.
The \UsePSPheader{} command must be specified before \UsePSspecialist{} is invoked. It allows the name of the dictionary file to be specified as the \filename{}. Normally it is sufficient to invoke \UsePSPheader{}, which will use the default dictionary name of \xypdf{} for the current version of \Xy-pic and \Xypic.

See the documentation for the specific driver to establish where the dictionary file should be located on any particular \TeX{} system. Usually it is sufficient to have a copy in the current working directory. Invoking the command \dumpPSSdict{} will place a copy of the requisite file, having the default name, in the current directory. This file will be used as the dictionary for the current processing, provided it is on the correct directory path, so that the driver can locate it when needed. Consult your local system administrator if you experience difficulties.

### 19.3 \texttt{PostScript} escape

An extra \texttt{(shape)} modifier key allows arbitrary \PostScript{} code to be applied to the current \object{}.

```
[!\texttt{(postscript code)}] for special effects
\texttt{[psxy]} stores current location.
```

Normally the \texttt{(postscript code)} will be a simple command to alter the \PostScript{} graphics state: e.g., \texttt{[!1 0 0 setrgbcolor]} changes the colour used to render parts of the \object{}. Any number of such \texttt{(shape)} modifiers is allowable, however it is more efficient to combine them into a single modifier, whenever possible.

It is very important that braces \{ and \} do not appear explicitly in any \postscript{} code, as this may upset the \Xy-pic \object{} parsing. However it is acceptable to have a control sequence name here, expanding into more intricate \PostScript{} code. This will not be expanded until a later (safe) time.

Due to differences within the DVI-drivers, such simple \PostScript{} commands need not affect every part of an \object{}. In particular the lines, curves and arrowheads generated by \Xy-pic use a different mechanism, which should give the same result with all drivers. This involves redefining some \PostScript{} procedures which are always read prior to rendering one of these objects. One simple way to specify a red line is as follows; the \texttt{xycolor} extension provides more sophisticated support for colour. The \texttt{(shape)} modifiers described in the previous section also use this mechanism, so should work correctly with all drivers.

```
def\xycolor(#1){%
/xycolor(#1 setrgbcolor)def
...\connect[!\texttt{xycolor(1 0 0)}]|dir{-}...
```

Note how the braces are inserted within the expansion of the control sequence \texttt{xycolor}, which happens after parsing of the \connection{}. The following table shows which graphics parameters are treated in this way, their default settings, and the type of \PostScript{} code needed to change them.

<table>
<thead>
<tr>
<th>Colour</th>
<th>\texttt{/xycolor(0 setgray)def}</th>
</tr>
</thead>
<tbody>
<tr>
<td>Line width</td>
<td>\texttt{/xywidth{.4 setlinewidth}def}</td>
</tr>
<tr>
<td>Dashing</td>
<td>\texttt{/xvdash{[] 0 setdash}def}</td>
</tr>
<tr>
<td>Line cap</td>
<td>\texttt{/xycap{1 setlinecap}def}</td>
</tr>
<tr>
<td>Line join</td>
<td>\texttt{/xyjoin{1 setlinejoin}def}</td>
</tr>
</tbody>
</table>

This feature is meant primarily for modifying the rendering of objects specified in \TeX{} and \Xy-pic, not for drawing new objects within \PostScript{}. No guarantee can be given of the current location, or scale, which may be different with different drivers. However a good \PostScript{} programmer will be able to overcome such difficulties and do much more. To aid in this the special modifier \texttt{[psxy]} is provided to record the location where the reference point of the current \object{} will be placed. Its coordinates are stored with keys \texttt{xypx} and \texttt{xyyp}.

### 19.4 Extensions

Several included file handle standard extensions.

- **xyps-l.tex** This included file (version 2.9) provides \Xypic support for the effects defined in the \texttt{line} extension.
- **xyps-c.tex** This included file (version 2.9) provides \Xypic support for the effects defined in the \texttt{color} extension.
- **xyps-r.tex** This included file (version 2.9) provides \Xypic support for the effects defined in the \texttt{rotate} extension.

### Answers to all exercises

**Answer to exercise 1 (p.5):** In the default setup they are all denote the reference point of the \Xy-pic picture but the cartesian coordinate \texttt{(pos) (0, 0)} denotes the point \texttt{origo} that may be changed to something else using the \texttt{:} operator.
Answer to exercise 2 (p.5): Use the \( \text{pos}\)ition \( <X,Y,+"ob".\)

Answer to exercise 3 (p.7): It first sets \( c \) according to \(...\). Then it changes \( c \) to the point right of \( c \) at the same distance from the right edge of \( c \) as its width, \( w \), i.e.,
\[
\begin{array}{c}
\text{The } \ldots \nwarrow \times \\
\quad w \\
\end{array}
\]

Answer to exercise 4 (p.8): The \( \langle \text{coord} \) \( "A";"B"; "C";"D", \( x \rangle \) returns the cross point. Here is how the author typeset the diagram in the exercise:
\[
\text{\textbackslash xy}
\%
\text{\% set up and mark A, B, C, and D:}
\text{(0,0)="A" *\textbackslash cir\{pt{+!DR\{A},}
\text{(7,10)="B" *\textbackslash cir\{pt{+!DR\{B},}
\text{(13,8)="C" *\textbackslash cir\{pt{+!DL\{C},}
\text{(15,4)="D" *\textbackslash cir\{pt{+!DL\{D},}
\%
\text{\% goto intersection and name+circle it:}
\text{"A","B","C","D",x} ="I" *\textbackslash cir\{3pt{+\{
\%
\text{\% make dotted lines:}
\text{"I","A"} */1pc;/-1pc/ **\textbackslash dir\{.\},}
\text{"I","D"} */1pc;/-1pc/ **\textbackslash dir\{.\}
\%
\endxy
\]

Answer to exercise 5 (p.8): To copy the \( p \) value to \( c \), i.e., equivalent to \( \text{"p".}\)

Answer to exercise 6 (p.8): When using the kernel connections that are all straight there is no difference, e.g., \( **\{\{< \) and \( **\{\}+E \) denote exactly the same position. However, for other connections it is not necessarily the case that the point where the connection enters the current object, denoted by \( ?<, \) and the point where the straight line from \( p \) enters the object, denoted by \( +E, \) coincide.

Answer to exercise 7 (p.8): The code typeset the picture
\[
\text{Box}
\]

Answer to exercise 8 (p.9): \( s_0 \) contains \( D \) and \( s_1 \) is the same as \( s\\text{\textbackslash sdepth} \) and contains \( A.\)

Answer to exercise 9 (p.9): This does the job, saving each point to make the previous point available for the next piece:
\[
\text{\textbackslash xy}
\text{\{\textbackslash p@\{0,-10 \textbackslash p@\{10,3 \textbackslash p@\{20,-5,\}
\text{s0=\"prev\}\textbackslash p@\{;\textbackslash p@\{;**\textbackslash dir\{-\}=\"prev\}\endxy
\]

Notice how we first save \( s_0 \) because that will be the last point that we run through thus the line is closed.

Answer to exercise 10 (p.11): The first typesets \( \text{"a"} \) centered around \( 0 \) and then moves \( c \) to the lower right corner, the second typesets \( \text{"a"} \) above the \( 0 \) point and does not change \( c \). With a \( \text{"."} \) at \( 0 \) they look like this: \( \text{"a"} \) and \( \text{"a"} \).

Answer to exercise 11 (p.11): They have the outlines
\[
\begin{array}{c}
\text{E} \\
\text{B}
\end{array}
\]

because the first is enlarged by the positive offset to the upper right corner and the second by the negative offset to the lower left corner.

Answer to exercise 12 (p.11): The first has no effect since the direction is set to be that of a vector in the current direction, however, the second reverses the current direction.

Answer to exercise 13 (p.13): One way is
\[
\text{\textbackslash xy}
\text{\{\textbackslash p@\{6,3\}+\{\}*{} ?(1)}
\text{*\textbackslash dir\{-\} */-5pt/\textbackslash dir\{-\}}
\text{*-*\textbackslash dir\{-\} */-5pt/\textbackslash dir\{-\} \endxy
\]

Thus we first create the two \( +\) s as \( p \) and \( c \) and connect them with the dummy connection \( **\{\} \) to setup the direction parameters. Then we move 'on top of c' with \( ?(1) \) and position the four sides of the square using \( ^\text{\textbackslash up} \) and \( _\text{\textbackslash down} \) for local direction changes and \( /\text{\textbackslash dimen}/ \) for skewing the resulting object by moving its reference point in the opposite direction.

Answer to exercise 14 (p.15): One way is to add extra half circles skewed such that they create the illusion of a shade:
\[
\text{\textbackslash xy}
\text{*\textbackslash cir\{5pt\}}
\text{*!\textbackslash p@\{-2pt,2pt\}\textbackslash cir\{5pt\}\{dr\text{-ul}\}}
\text{*!\textbackslash p@\{-4pt,4pt\}\textbackslash cir\{5pt\}\{dr\text{-ul}\}}
\text{*!\textbackslash p@\{-6pt,6pt\}\textbackslash cir\{5pt\}\{dr\text{-ul}\} \endxy
\]
Answer to exercise 15 (p.17): This is the code that was actually used:
```latex
xy (0.20)*{0}+{0};(60.00)*{0}+(B)="B"
\curve\{ \POS(4.0)^{+}+\UR(0),"B"
\curve(30,30)\POS^++\ID(1),"B"
\curve(20,40\&(40,40))\POS^++\ID(2),"B"
\curve(10,20\&(30,20)\&(50,-20)\&(60,-10)\POS^+!\UR(4)\endxy
```

Answer to exercise 16 (p.17): This is the code that was used to typeset the picture:
```latex
xy (0.20)**{A};(60.00)**{B}
\curve\{ 10.20\&(30,20)\&(50,-20)\&(60,-10)\POS
?<(1.0)*\dir<-a " ?(1.0)*\dir>="h"
?(.1)*\dir<-b " ?(0.9)*\dir>="i"
?(.2)*\dir<-c " ?(0.8)*\dir>="j"
?(.3)*\dir<-d " ?(.7)*\dir>="k"
?(.4)*\dir<-e " ?(.6)*\dir>="l"
?(.5)*\dir<>("f","a"!\RC\txt\{\ssz\{\lt\})\txt\{\ssx\ssz\},\txt\{\ssz\ssx\{\lt\})"!
\"b"+!\RD\txt\{\ssz\{\lt\})\txt\{\ssx\ssz\},\txt\{\ssz\ssx\{\lt\})",\txt\{\ssz\ssx\{\lt\})","i"!\LC\txt\{\ssz\\{\lt\})\txt\{\ssx\ssz\},\txt\{\ssz\ssx\{\lt\})","c"!\RD\txt\{\ssz\{\lt\})\txt\{\ssx\ssz\},\txt\{\ssz\ssx\{\lt\})","j"!\LC\txt\{\ssz\{\lt\})\txt\{\ssx\ssz\},\txt\{\ssz\ssx\{\lt\})","d"!\RD\txt\{\ssz\{\lt\})\txt\{\ssx\ssz\},\txt\{\ssz\ssx\{\lt\})","k"!\LC\txt\{\ssz\{\lt\})\txt\{\ssx\ssz\},\txt\{\ssz\ssx\{\lt\})","e"!\RD\txt\{\ssz\{\lt\})\txt\{\ssx\ssz\},\txt\{\ssz\ssx\{\lt\})","1"!\RD\txt\{\ssz\{\lt\})\txt\{\ssx\ssz\},\txt\{\ssz\ssx\{\lt\})","f"+!\RD/-3pt\{\ssz\{\lt\})\endxy
```

Answer to exercise 17 (p.17): Here is the code that was used to typeset the picture:
```latex
\def\ssz#1\{\bbox{\cdot#1}\}
\xy (0.00)**{A};(30,-10)**{B}="B","**\dir<-",  
"B"\curve(30,20\&(20,25)\&(35,20))\POS  
?(0.0)*\dir<-a " ?(1.0)*\dir>="h"
?(.1)*\dir<-b " ?(0.9)*\dir>="i"
?(.2)*\dir<-c " ?(0.8)*\dir>="j"
?(.3)*\dir<-d " ?(.7)*\dir>="k"
?(.4)*\dir<-e " ?(.6)*\dir>="l"
?(.5)*\dir<>("f","a"!\RC\txt\{\ssz\{\lt\})\txt\{\ssx\ssz\},\txt\{\ssz\ssx\{\lt\})","h"!\LC\txt\{\ssz\\{\lt\})\txt\{\ssx\ssz\},\txt\{\ssz\ssx\{\lt\})","b"!\RD\txt\{\ssz\{\lt\})\txt\{\ssx\ssz\},\txt\{\ssz\ssx\{\lt\})","i"!\LC\txt\{\ssz\\{\lt\})\txt\{\ssx\ssz\},\txt\{\ssz\ssx\{\lt\})","c"!\RD\txt\{\ssz\{\lt\})\txt\{\ssx\ssz\},\txt\{\ssz\ssx\{\lt\})","j"!\LC\txt\{\ssz\\{\lt\})\txt\{\ssx\ssz\},\txt\{\ssz\ssx\{\lt\})","d"!\RD\txt\{\ssz\{\lt\})\txt\{\ssx\ssz\},\txt\{\ssz\ssx\{\lt\})","k"!\LC\txt\{\ssz\\{\lt\})\txt\{\ssx\ssz\},\txt\{\ssz\ssx\{\lt\})","e"!\RD\txt\{\ssz\{\lt\})\txt\{\ssx\ssz\},\txt\{\ssz\ssx\{\lt\})","1"!\RD\txt\{\ssz\{\lt\})\txt\{\ssx\ssz\},\txt\{\ssz\ssx\{\lt\})","f"+!\RD/-3pt\{\ssz\{\lt\})\endxy
```

Answer to exercise 18 (p.19): Here is how:
```latex
\xy (0.0,0)**{A} \*{\frm[0]};  
(10.7)**{B} \*{\frm[0]} \*{\frm[.]}\endxy
```

Answer to exercise 19 (p.19): The \*{\cir} operation changes c to be round whereas \*{\frm[0]} does not change c at all.

Answer to exercise 20 (p.19): Here is how:
```latex
\xy (0.0,0)**{A};  
(10.7)**{B} \*{\frm[.]}\endxy
```

The trick in the last line is to ensure that the reference point of the merged object to be braced is the right one in each case.

Answer to exercise 21 (p.22): This is how the author specified the diagram:
```latex
\UseCrayolaColors
\$\xy\drop[1.26]\xybox{\POS
(0.0)*{A};(100,40)*{B}**
?<<\[0,\] [red][0]<5pt\{\heartsuit\};
?>>\[0,\] [1.3pt][thicker] \dir\}
?(.1)*[Left]!RD\txt\{\label 1\}*{\[red\}\frm[.]}.
?(.2)*[!Lsave newpath
\xyXpos xyYpos moveto 50 dup rlineto
20 setlinewidth 0 0 1 setrgbcolor stroke
\restore[\psxy{.}],
?(.2)*[0]\txt\{\label 2\}*{\[red\]\frm[.],
?(.2)*[\BurntOrange]{*},
?(.3)*[halfsize] \txt\{\label 3\}*{\[red\]\frm[.,
?(.375)*{\flip}\txt\{\label 4\}*{\[red\]\frm[.],
?(.5)*{\dbsize} \txt\{\label 5\}*{\[red\]\frm[.],
?(.5)*[\WildStrawberry]{*},
?(.7)*{\hfip}\txt\{\label 6\}*{\[red\]\frm[.],
?(.8)*{\vflip}\txt\{\label 7\}*{\[red\]\frm[.],
?(.9)*[\right]!LD\txt\{\label 8\}*{\[red\]\frm[.],
?(.5)*{[0].\,66667}/30pt/\txt\{special effect: aligned text\}
*{\[red\]\frm[.]}\endxy
```

Answer to exercise 22 (p.25): A modifier was used to make all entries round and all entries had an extra circle added (these things are independent). Finally the matrix was rotated to make it possible to enter it as a simple square:
```latex
\entrymodifiers={|o=<1pc>}
\everyentry{\drop{\cir\{}}
\xy\xymatrix@ur{  
A \save[];[r] \*{\dir\}-,
\B \restore\save[];[d] \*{\dir\}-
\endxy}
```

Answer to exercise 23 (p.25): The \*{\cir} operation changes c to be round whereas \*{\frm[0]} does not change c at all.

Answer to exercise 24 (p.25): The author did not specify the \*{\cir} operation changes c to be round whereas \*{\frm[0]} does not change c at all.

Answer to exercise 25 (p.25): The author did not specify the \*{\cir} operation changes c to be round whereas \*{\frm[0]} does not change c at all.

Answer to exercise 26 (p.25): The author did not specify the \*{\cir} operation changes c to be round whereas \*{\frm[0]} does not change c at all.
Notice the use of a + modifier to ensure that the entries are grown just as in the default case.

Answer to exercise 24 (p.25): Here is how:
```
\textbf{Answer to exercise 28 (p.29):} The author used
\newdir{}>{*+<+5pt\dir{>}}
```

Answer to exercise 29 (p.30): The author used
```
\textbf{Answer to exercise 30 (p.30):} The author used
\textbf{Answer to exercise 31 (p.32):} Here is the code used to typeset the 	extit{pasing diagram} in figure 13.
```

Answer to exercise 25 (p.28): Here is what the author did:
```
\textbf{Answer to exercise 26 (p.28):} The author did
```

Answer to exercise 27 (p.29): Here is the entire \texttt{xy}-picture of the exercise:
```
\textbf{Answer to exercise 28 (p.29):} The author used
\newdir{}>{*+<+5pt\dir{>}}
```

For the straight arrows, it would have been simpler to use \texttt{\textbackslash .to} provided \texttt{xyarrow} has been loaded. Instead \texttt{\textbackslash .twocell<0>\{\omit\}} was used to illustrate the versatility of nudging and \texttt{\omit} ; thus \texttt{xy2cell} can completely handle a wide range of diagrams, without
Answer to exercise 32 (p.35): Here is the code used by the author to set the first diagram.
\begin{verbatim}
\uppercurveobject{{?}}
\lowercurveobject{{\circ}}
\ymatrixcolsep{5pc}
\ymatrixrowsep{2pc}
\begin{diagram}
\relax\txt{ FUN }\rtwocell<8>\{!\&}
& \relax\txt{ gaMES }
\end{diagram}
\end{verbatim}

Here is the code used for the second diagram.
\begin{verbatim}
\ymatrixcolsep{2.5pc}
\ymatrixrowsep{4pc}
\begin{diagram}
\relax\txt{<1.5cm}>\{\bf Ground State} \rtwocell<12>^{{+++/-\small continuous power}}_{\small pulsed emission}\{!\}
& \relax\txt{<1.5cm}\{\bf Excited State} \end{diagram}
\end{verbatim}
